Computer Networks: Architecture and Protocols

Lecture 9

Recap: Spanning Tree Protocol Fundamentals of Routing

Qizhe Cai

Goals for Today's Lecture

- Recap **Spanning Tree Protocol**
- **Why** do we need network layer?
 - **Why** not just use switched Ethernet across the Internet?
- **Fundamentals** of network layer
 - Routing tables
 - The **right** way to think about routing tables
- But, before that

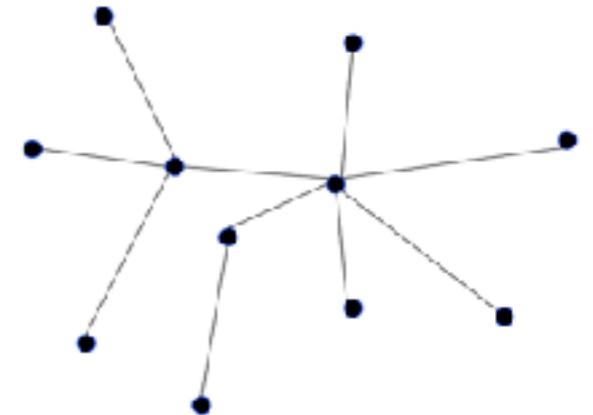

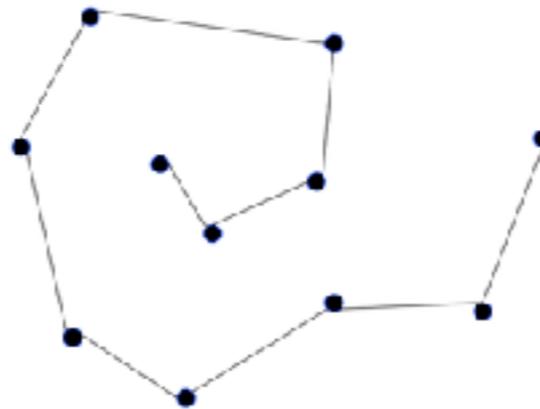

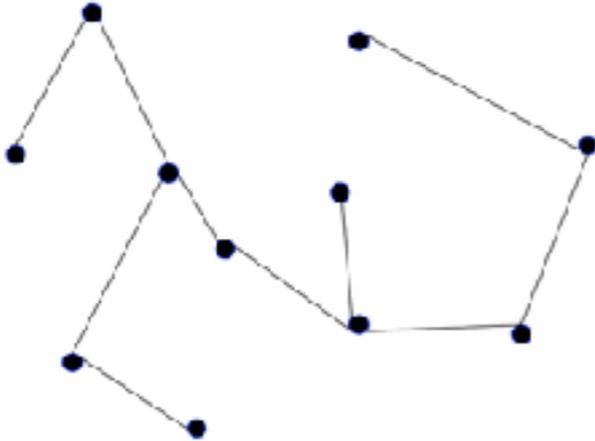

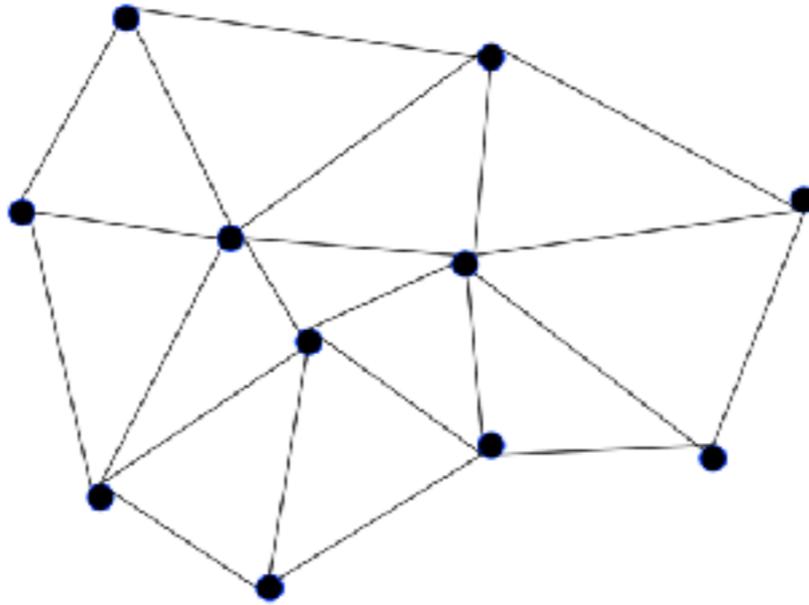

Recap of Link Layer so far

Recap: Link layer

- **Traditional Link Layer: Broadcast Ethernet**
- **CSMA/CD**
 - Random access on a broadcast channel
 - Exponential Backoff
- **Why Frames?**
 - To incorporate sentinel bits for identifying frame start/end
 - To incorporate link layer source and destination names
 - To incorporate CRC for checking correctness of received frames
- **Modern Link Layer: Switched Ethernet**
 - Why? Scalability limits of traditional Ethernet
 - Why? Detecting collisions on a broadcast channel

Recap: Spanning Tree definition

- **Subgraph that includes all vertices but contains no cycles**
 - Links not in the spanning tree are not used in forwarding frames

Recap: Spanning Tree Protocol

- **Messages (Y,d,X)**

- Proposing root Y; from node X; advertising a distance d to Y

- Initially each switch proposes itself as the root

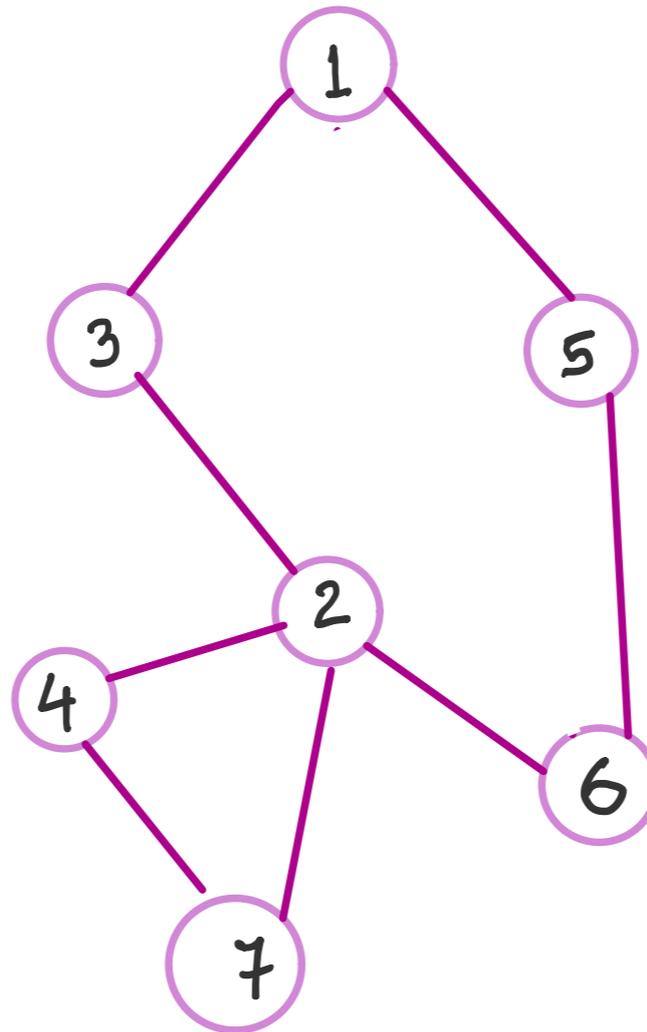

- that is, switch X announces (X,0,X) to its neighbors

- At each switch Z:

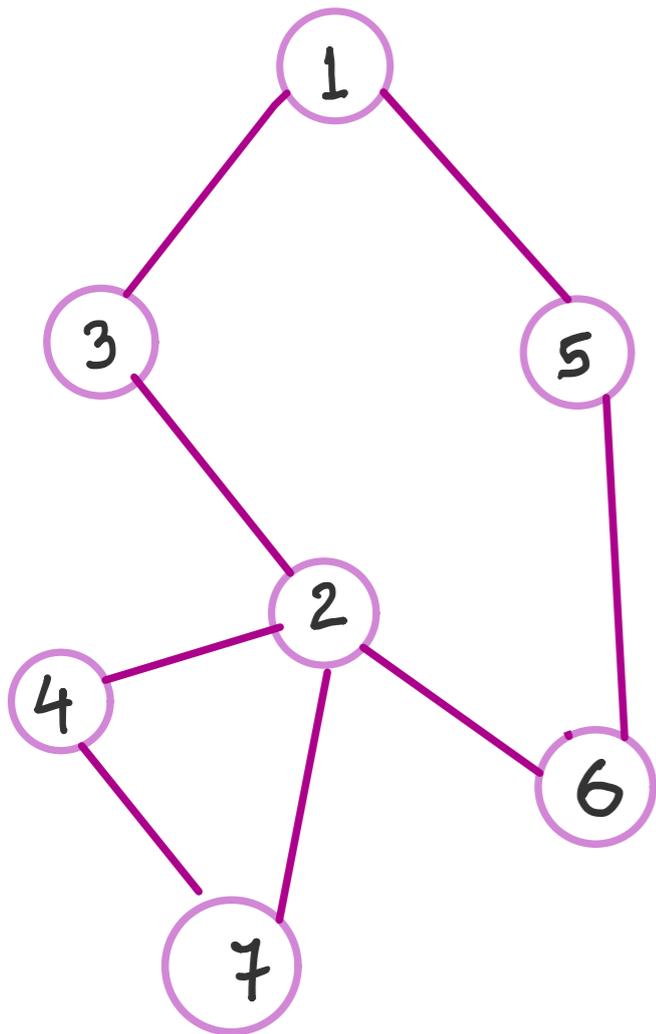

WHENEVER a message (Y,d,X) is received from X:

- IF Y's id < current root
 - THEN set root = Y; next-hop = X
- IF Shortest distance to root > d + distance_from_X
 - THEN set shortest-distance-to-root = d + distance_from_X
- IF **root changed OR shortest distance to the root changed:**
 - Send all neighbors message (Y, shortest-distance-to-root, Z)

**Lets run the Spanning Tree Protocol on this example
(assume all links have "distance" 1)**

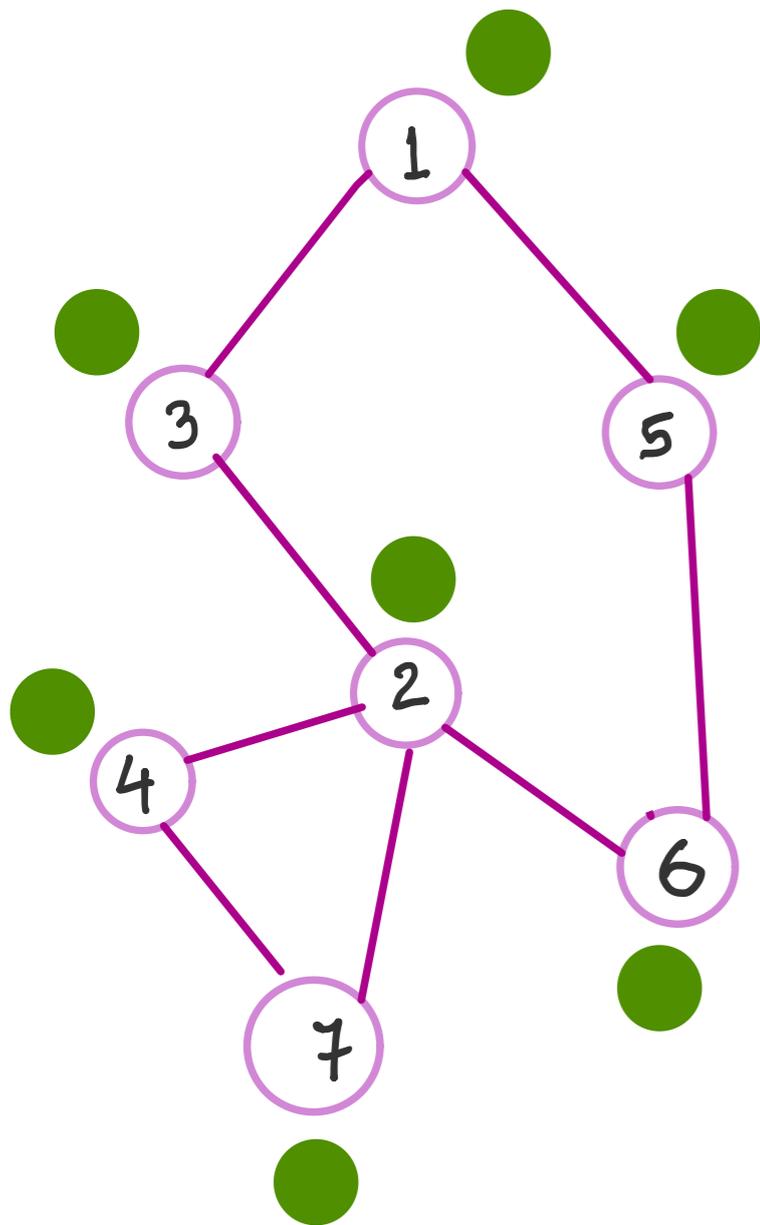

Round 1

	Receive	Send	Next-hop
1		(1, 0, 1)	1
2		(2, 0, 2)	2
3		(3, 0, 3)	3
4		(4, 0, 4)	4
5		(5, 0, 5)	5
6		(6, 0, 6)	6
7		(7, 0, 7)	7

Round 2

	Receive	Send	Next hop
1 (1, 0, 1)	(3, 0, 3), (5, 0, 5)		1
2 (2, 0, 2)	(3, 0, 3), (4, 0, 4), (6, 0, 6), (7, 0, 7)		2
3 (3, 0, 3)	(1, 0, 1), (2, 0, 2)	(1, 1, 3)	1
4 (4, 0, 4)	(2, 0, 2), (7, 0, 7)	(2, 1, 4)	2
5 (5, 0, 5)	(1, 0, 1), (6, 0, 6)	(1, 1, 5)	1
6 (6, 0, 6)	(2, 0, 2), (5, 0, 5)	(2, 1, 6)	2
7 (7, 0, 7)	(2, 0, 2), (4, 0, 4)	(2, 1, 7)	2

Round 3

	Receive	Send	Next hop
1	(1, 1, 3), (1, 1, 5)		1
2	(1, 1, 3), (2, 1, 4), (2, 1, 6), (2, 1, 7)	(1, 2, 2)	3
3 (1, 1, 3)			1
4 (2, 1, 4)	(2, 1, 7)		2
5 (1, 1, 5)	(2, 1, 6)		1
6 (2, 1, 6)	(1, 1, 5)	(1, 2, 6)	5
7 (2, 1, 7)	(2, 1, 4)		2

Round 4

	Receive	Send	Next hop
1			1
2 (1, 2, 2)	(1, 2, 6)		3
3	(1, 2, 2)		1
4	(1, 2, 2)	(1, 3, 4)	2
5	(1, 2, 6)		1
6 (1, 2, 6)	(1, 2, 2)		5
7	(1, 2, 2)	(1, 3, 7)	2

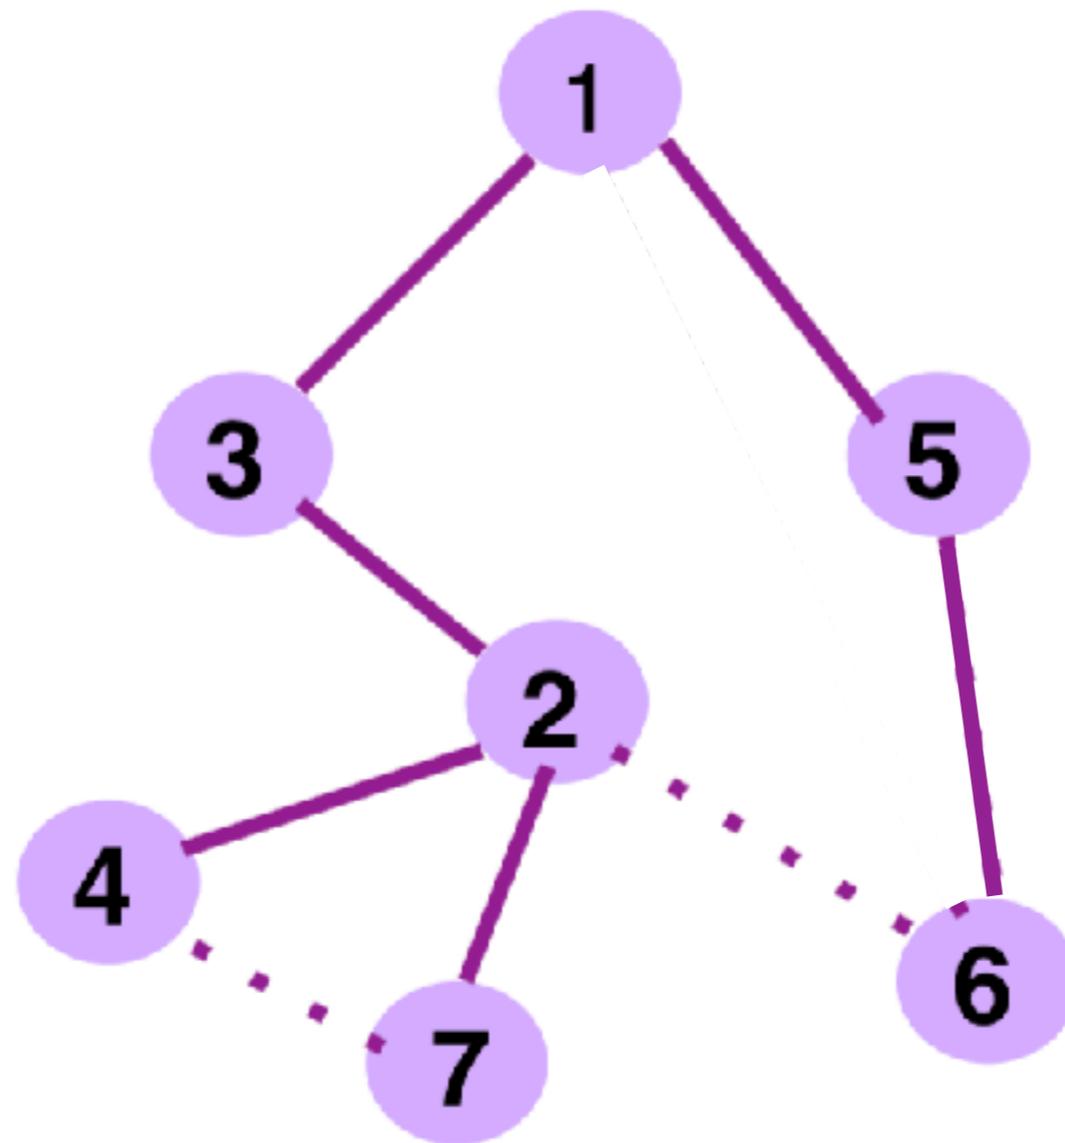

Round 5

	Receive	Send	Next hop
1			1
2	(1, 3, 4), (1, 3, 7)		3
3			1
4 (1, 3, 4)	(1, 3, 7)		2
5			1
6			5
7 (1, 3, 7)	(1, 3, 4)		2

After Round 5: We have our Spanning Tree

- 3-1
- 5-1
- 6-1
- 2-3
- 4-2
- 7-2

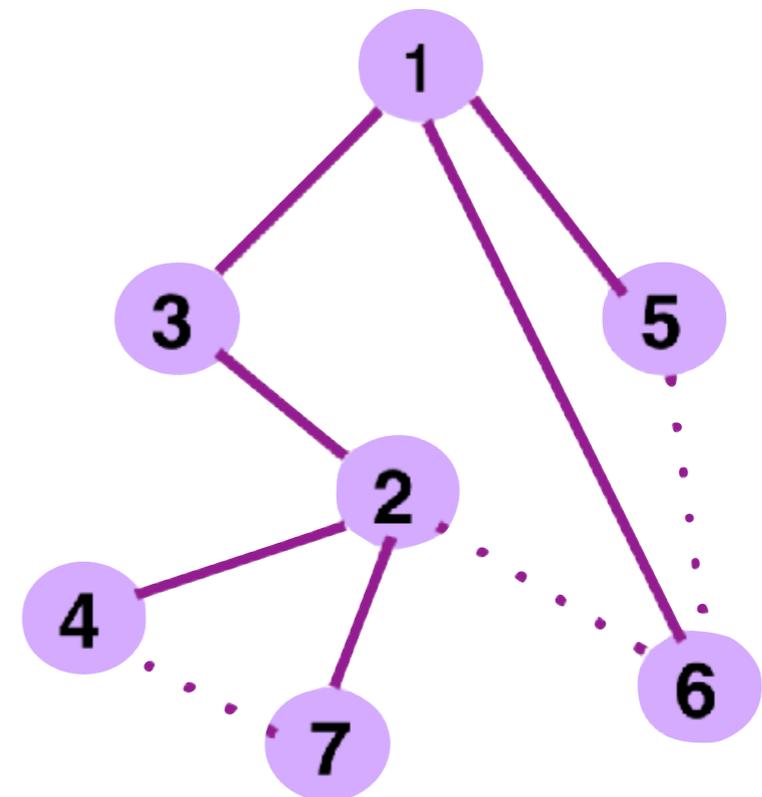

Spanning Tree Protocol ++ (incorporating failures)

- Protocol must react to **failures**
 - Failure of the root node
 - Failure of switches and links
- **Root node sends periodic announcement messages**
 - Few possible implementations, but this is simple to understand
 - Other switches continue forwarding messages
- Detecting failures through timeout (**soft state**)
 - If no word from root, time out and send a $(Y, 0, Y)$ message to all neighbors (in the graph)!
- **If multiple messages with a new root received, send message (Y, d, X) to the neighbor sending the message**

Example: Suppose link 2-4 fails

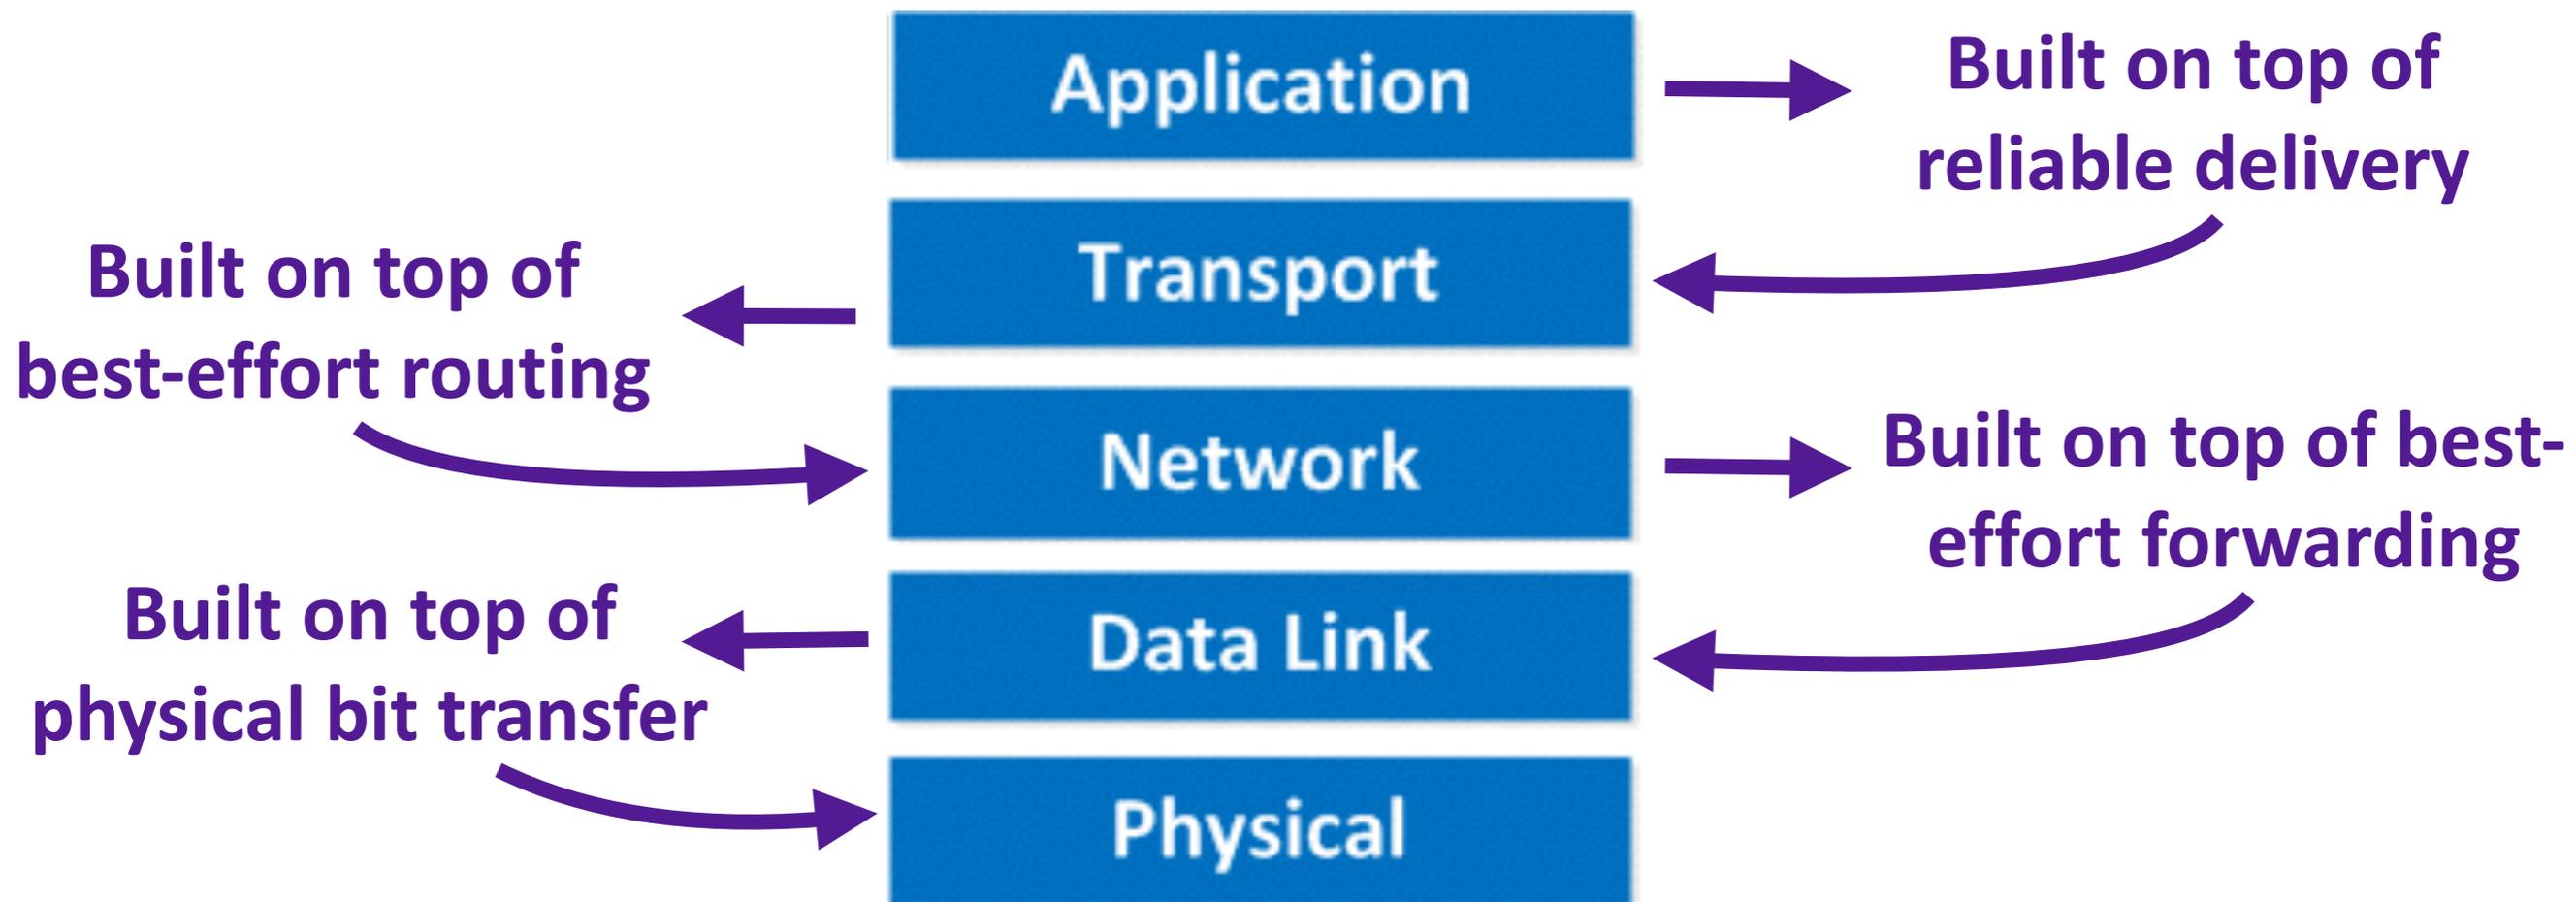

- 4 will send $(4, 0, 4)$ to all its neighbors
 - 4 will stop receiving announcement messages from the root
 - Why?
- At some point, 7 will respond with $(1, 3, 7)$
- 4 will now update to $(1, 4, 4)$ and send update message
- New spanning tree!

Questions?

The end of Link Layer

And the beginning of network layer :-D

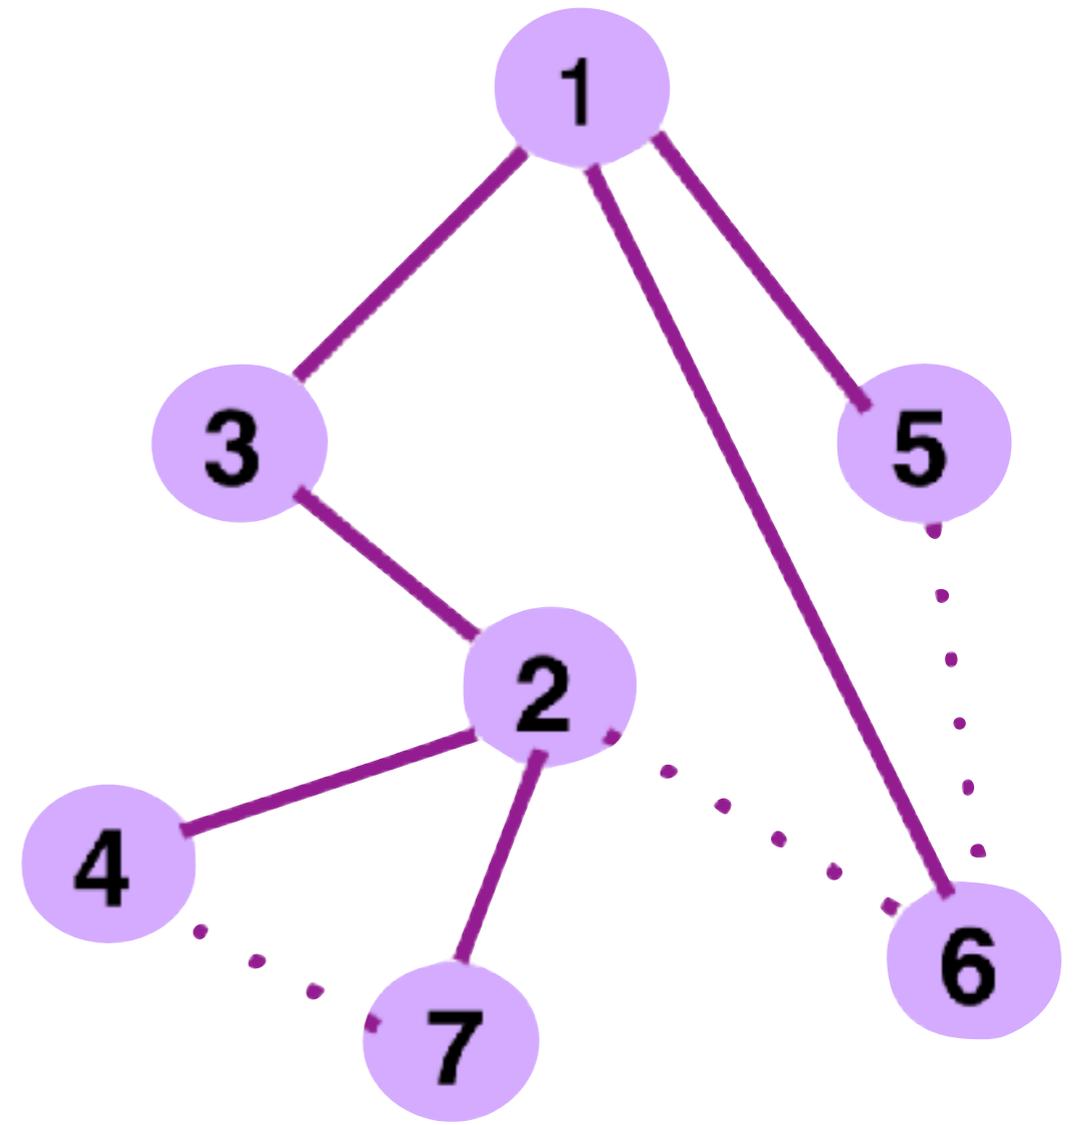

Why do we need a network layer?

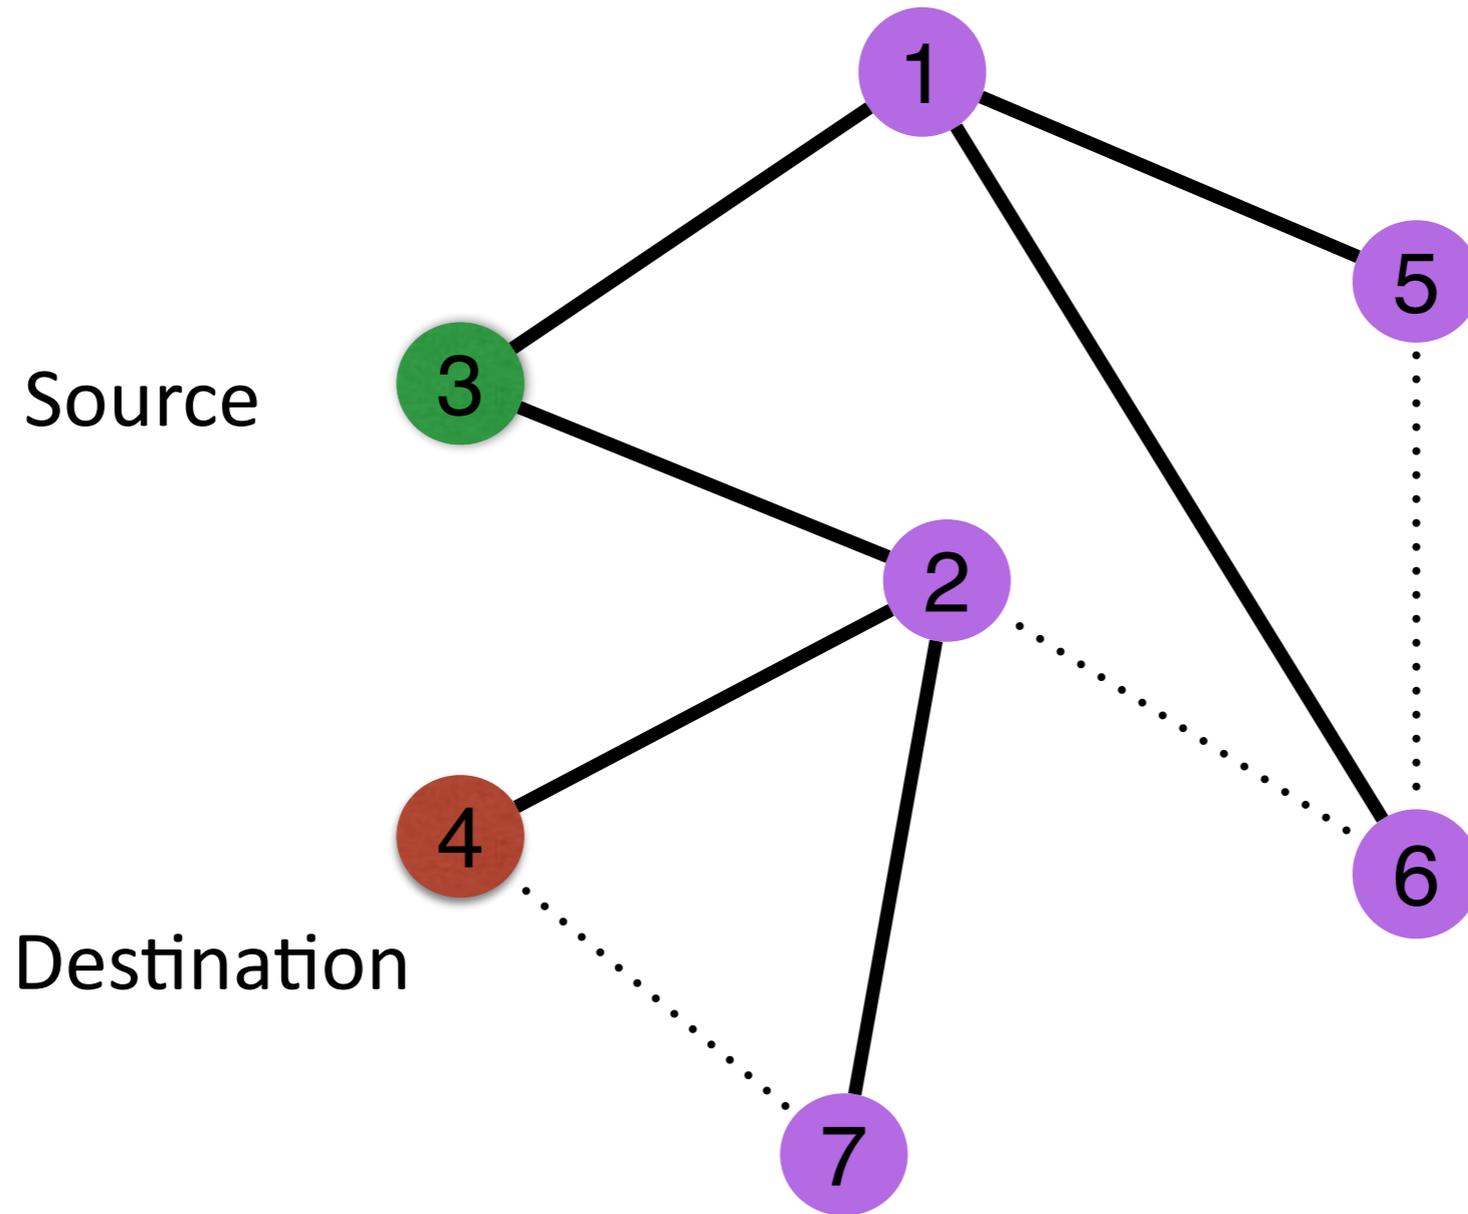

- Why not just use spanning trees across the entire network?
- Easy to design routing algorithms for (spanning) trees
 - **Nodes can “flood” packet to all other nodes**

Flooding on a Spanning Tree

- Sends packet to *every* node in the network
- **Step 1:** Ignore the links not belonging to the Spanning Tree
- **Step 2:** Originating node sends “flood” packet out every link (on spanning tree)
- **Step 3:** Send incoming packet out to all links **other than the one that sent the packet**

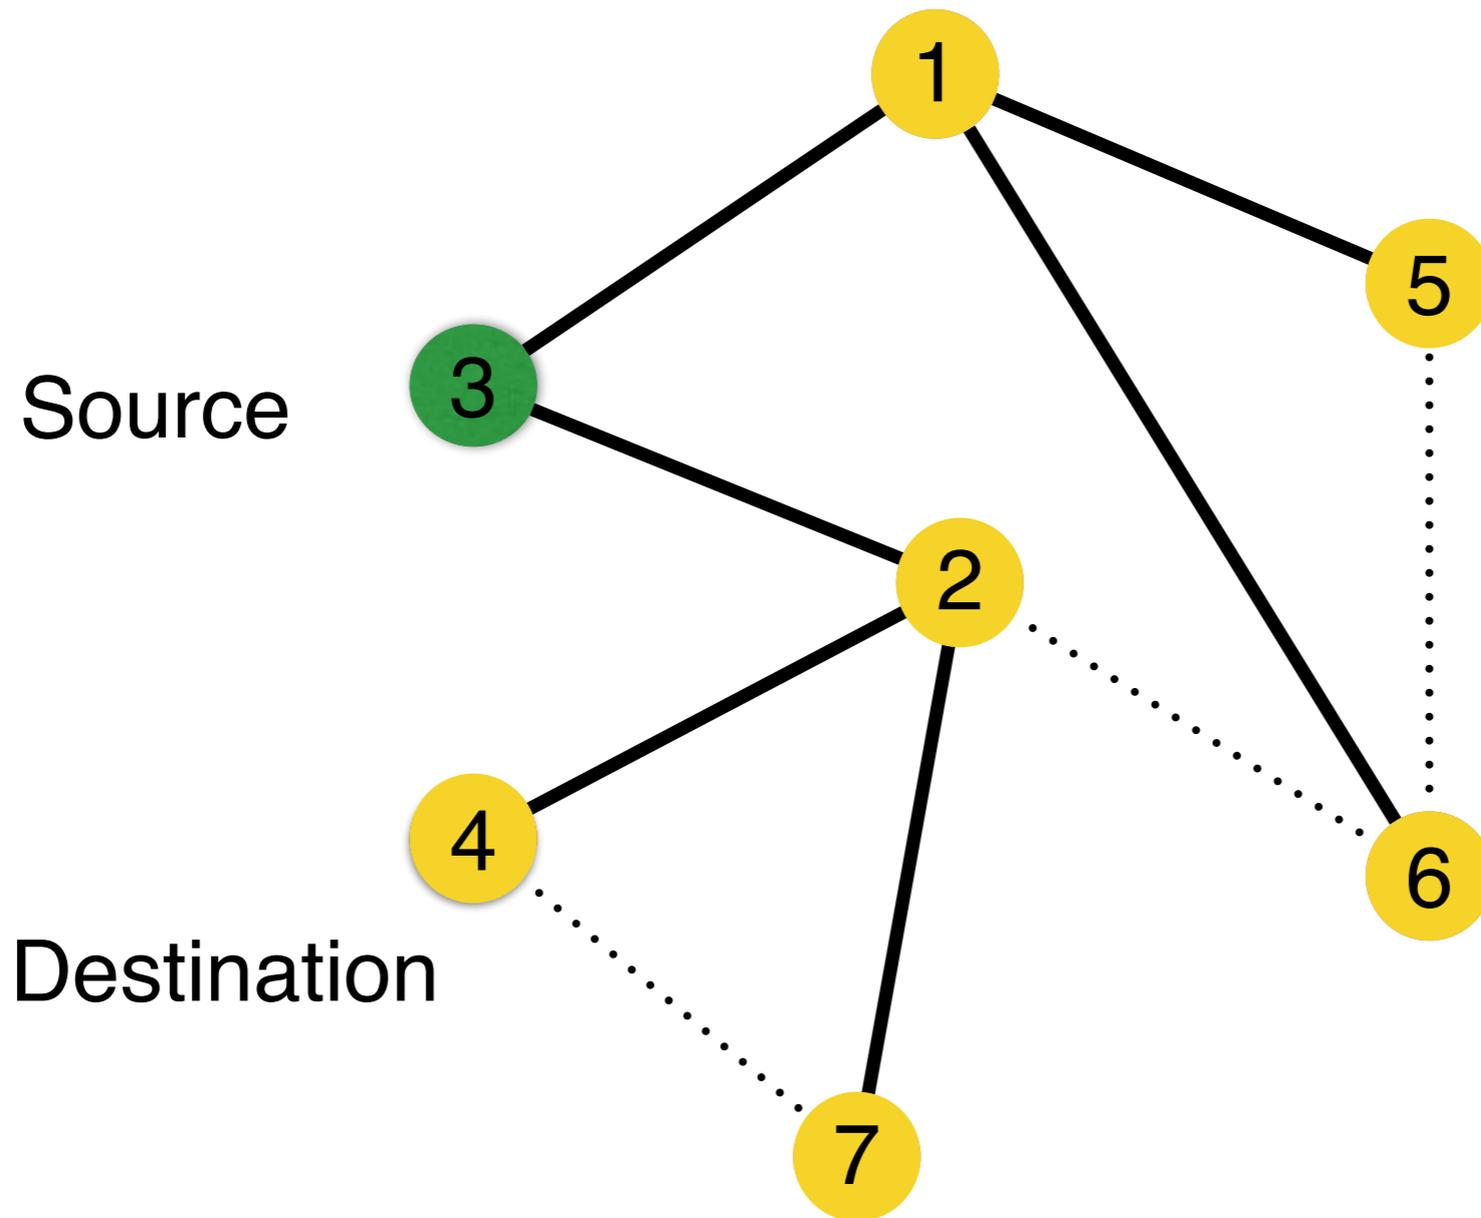

Flooding Example

Flooding Example

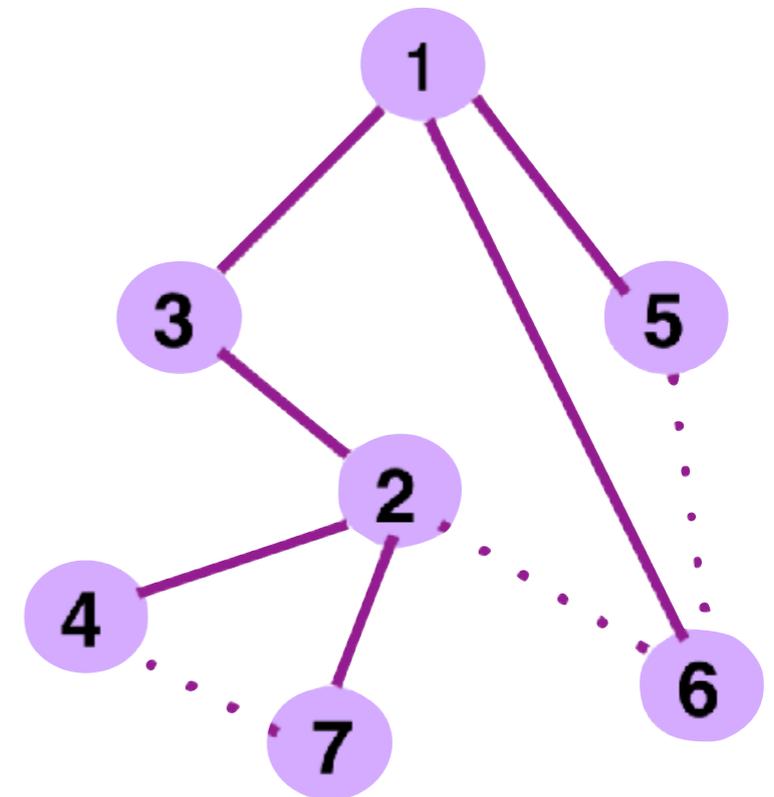

Eventually all nodes are covered

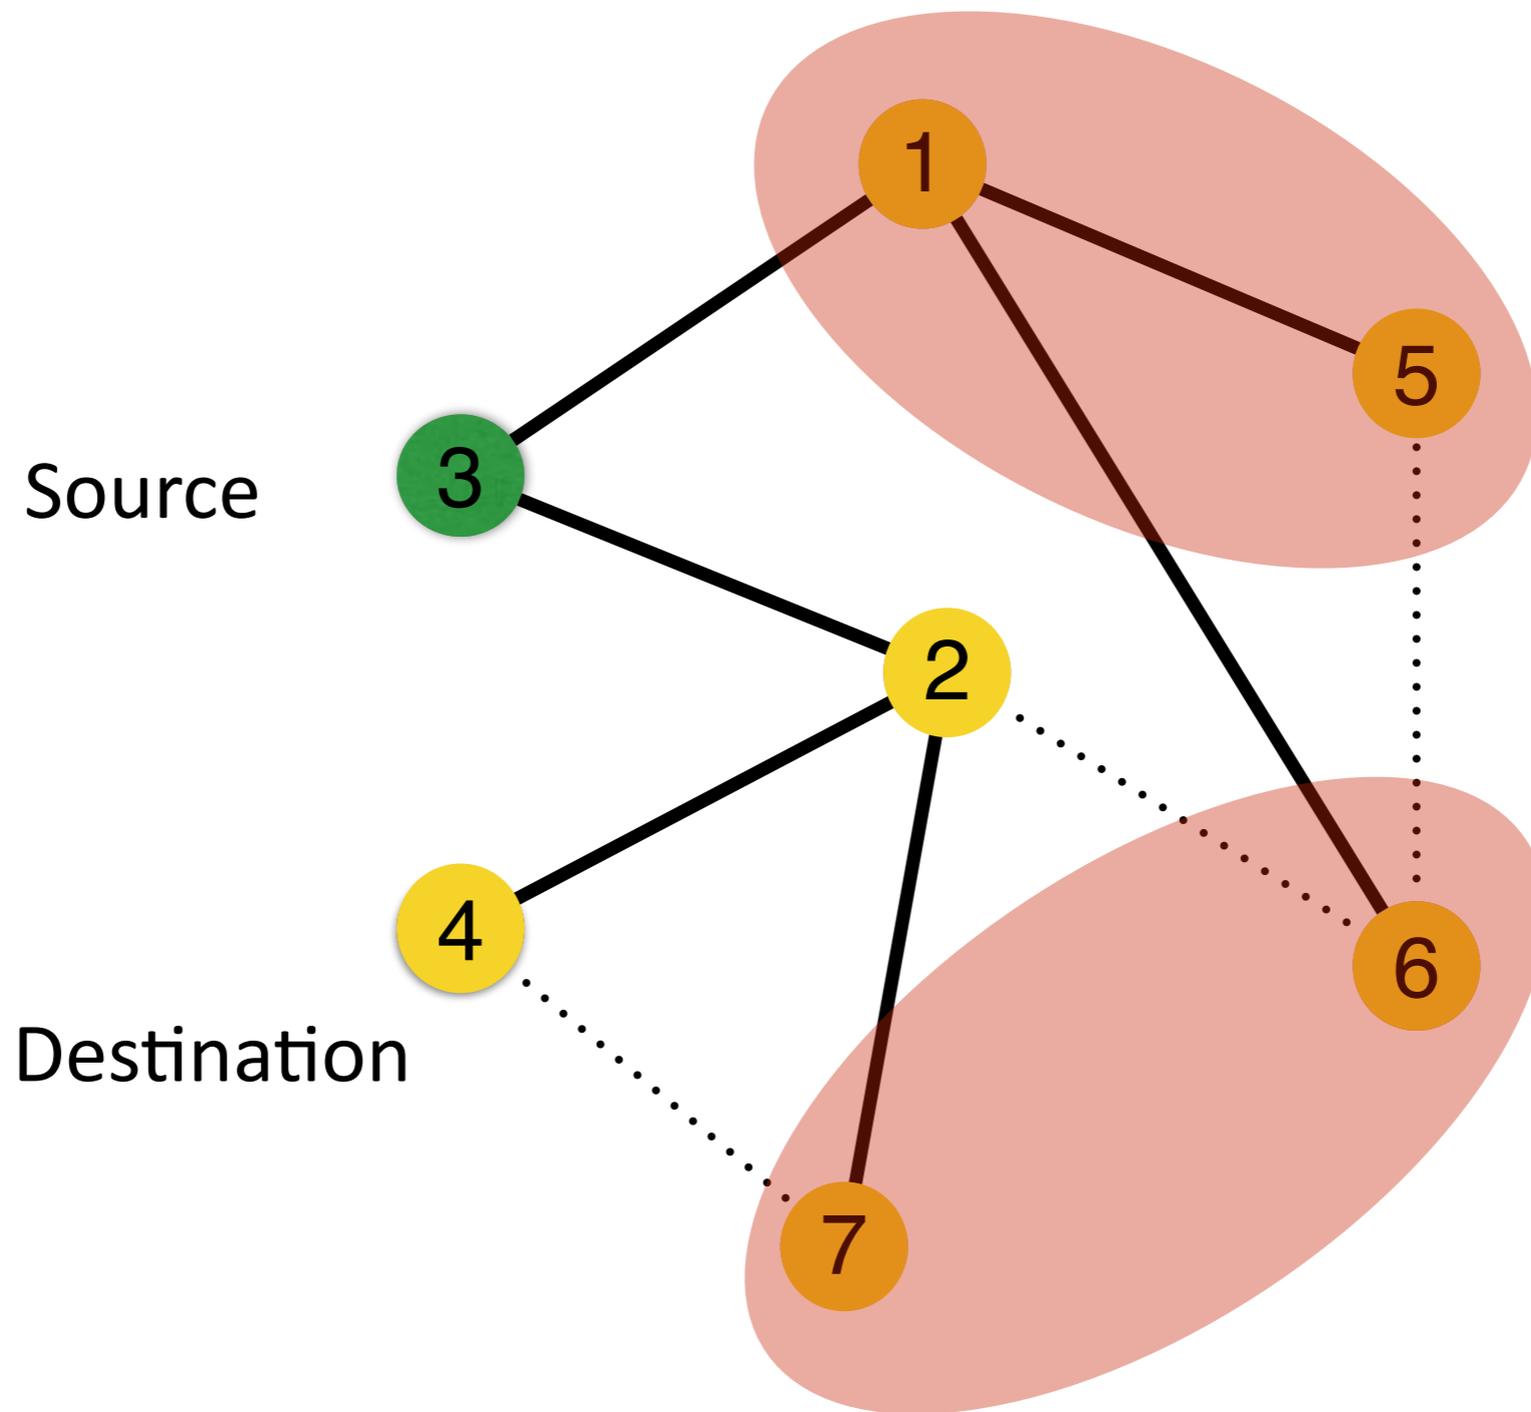

One copy of packet delivered to destination

Routing via Flooding on Spanning Tree ...

- Easy to design routing algorithms for trees
 - **Nodes can “flood” packet to all other nodes**
- Amazing properties:
 - No routing tables needed!
 - No packets will ever loop.
 - At least (and exactly) one packet must reach the destination
 - Assuming no failures

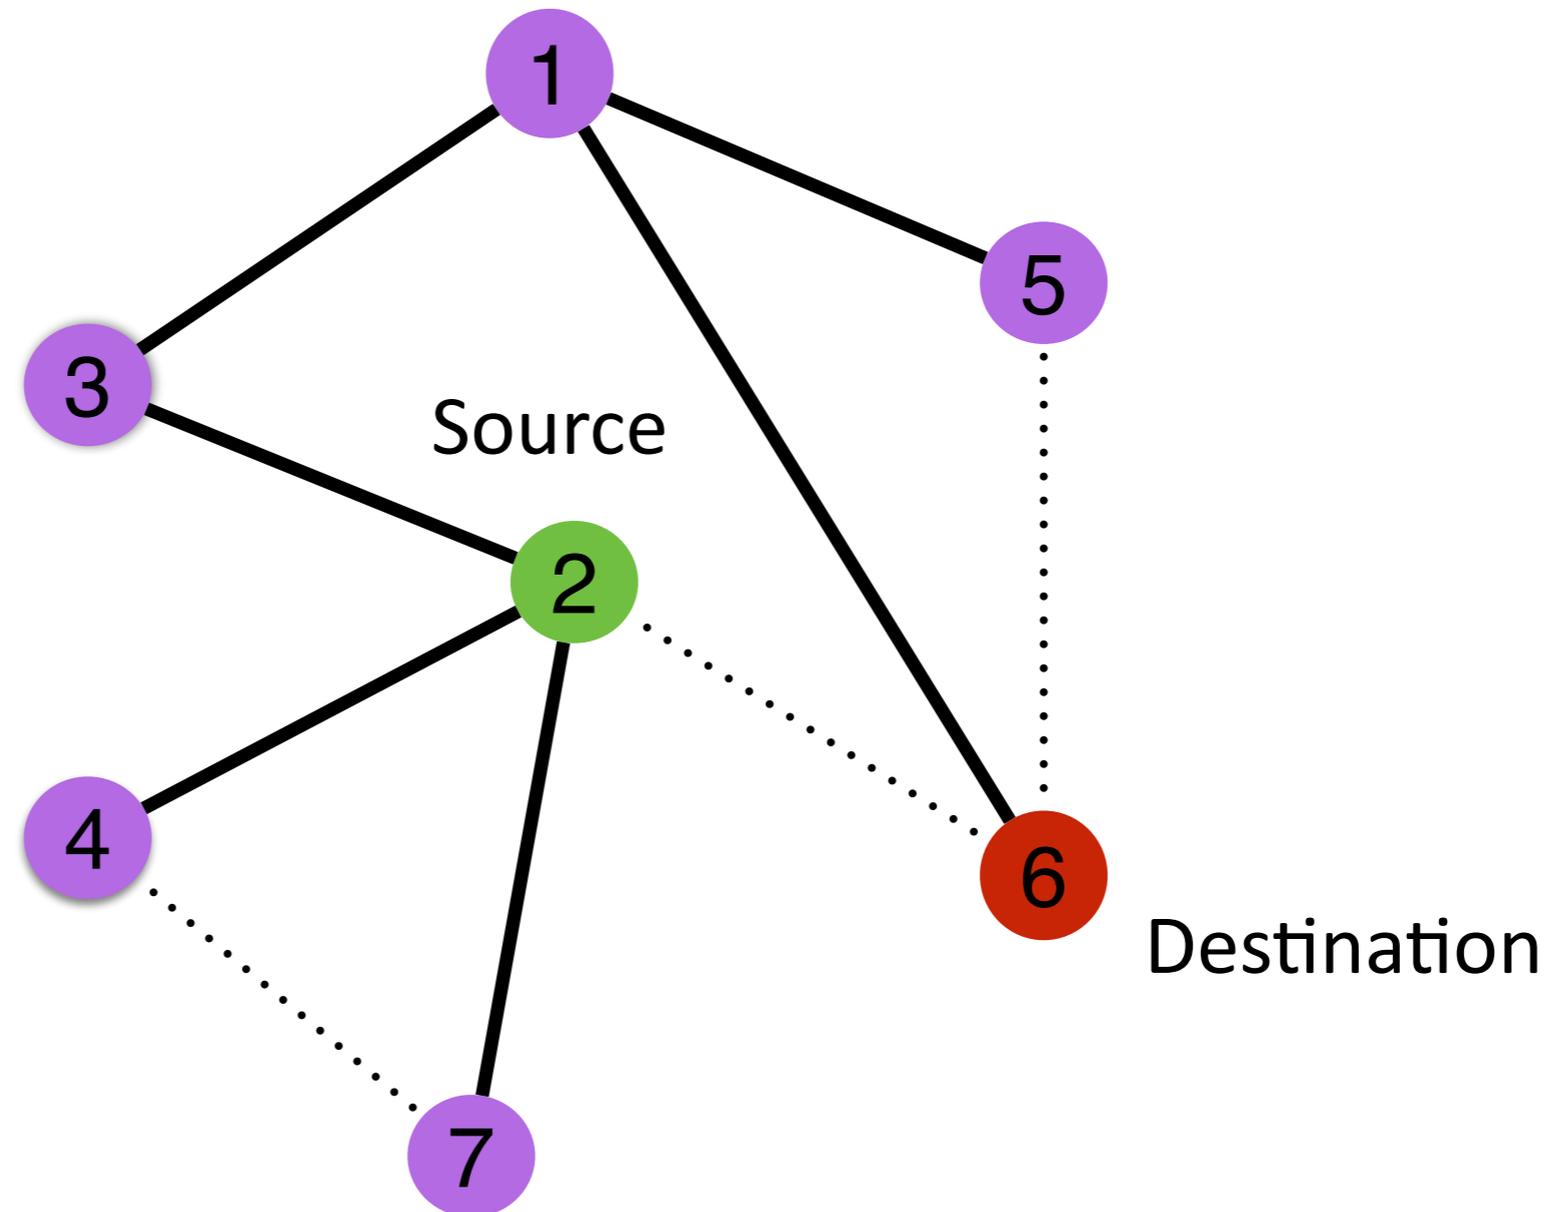

Three fundamental issues!

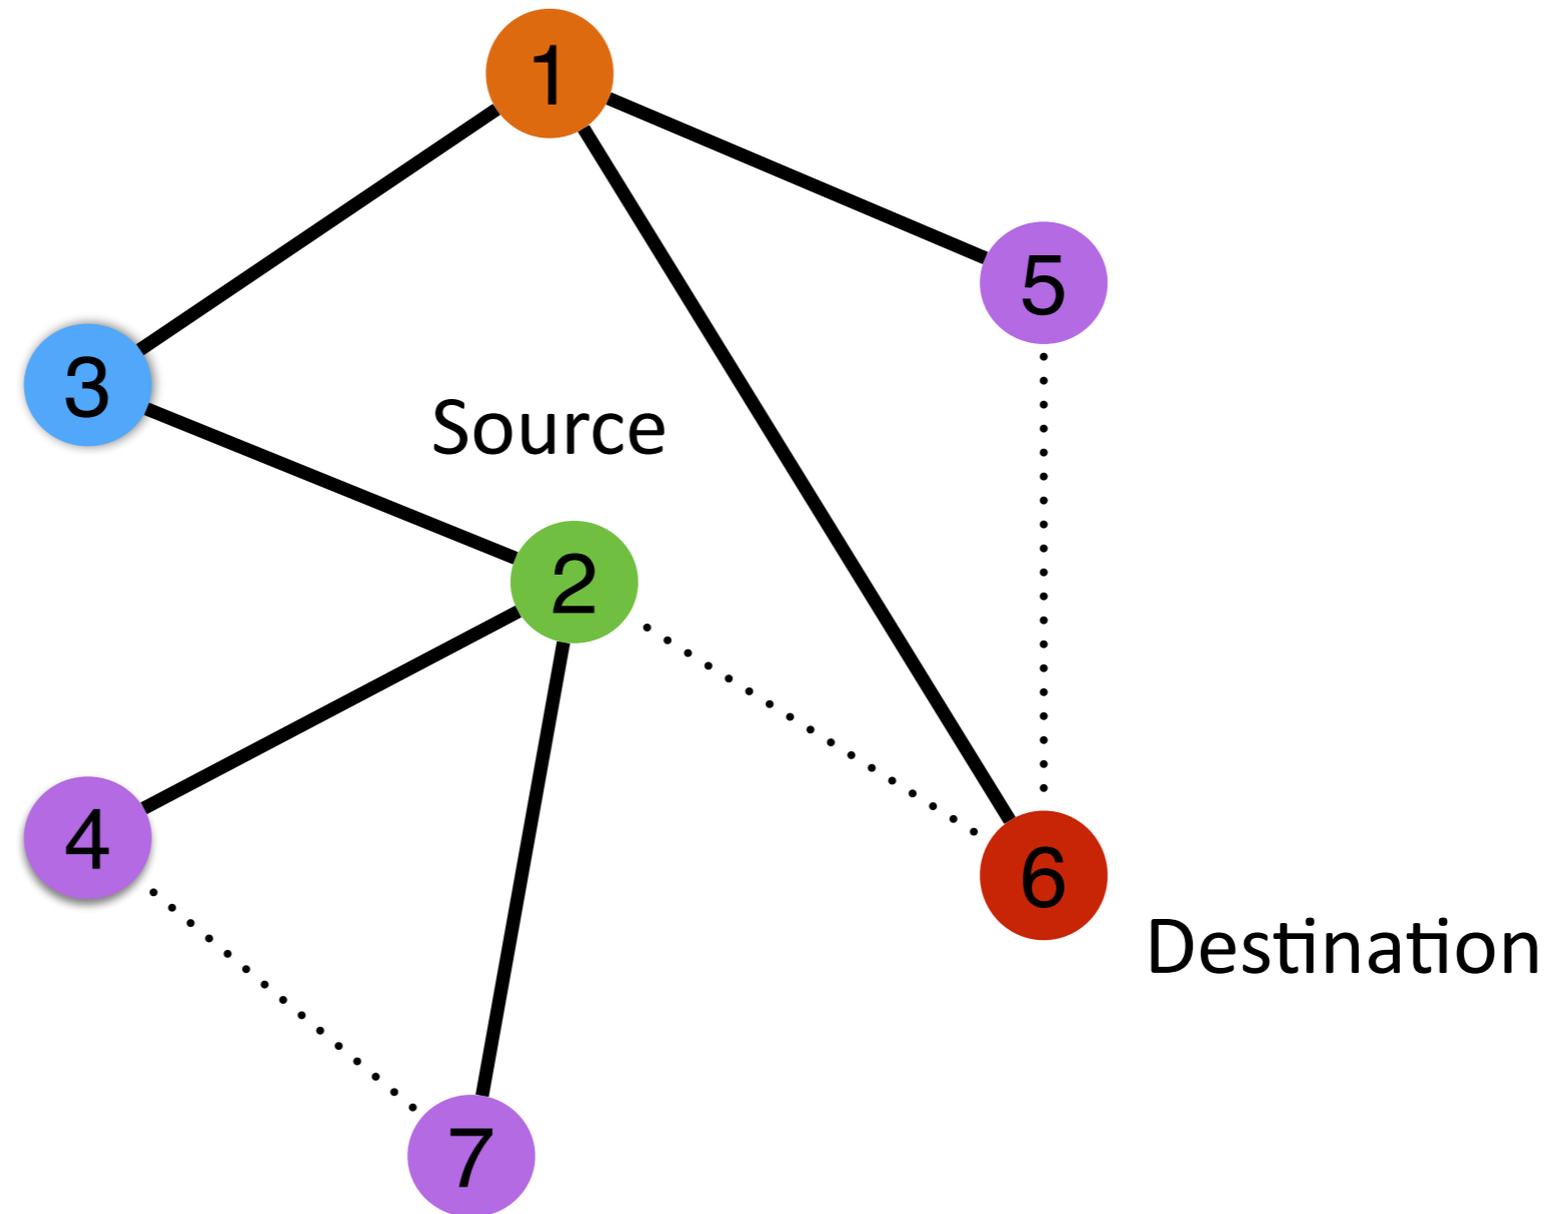

**Issue 1: Each host has to do unnecessary packet processing!
(to decide whether the packet is destined to the host)**

Three fundamental issues!

Issue 2: Higher latency!
(The packets unnecessarily traverse much longer paths)

Three fundamental issues!

Issue 3: Lower bandwidth availability!
(2-6 and 3-1 packets unnecessarily have to share bandwidth)

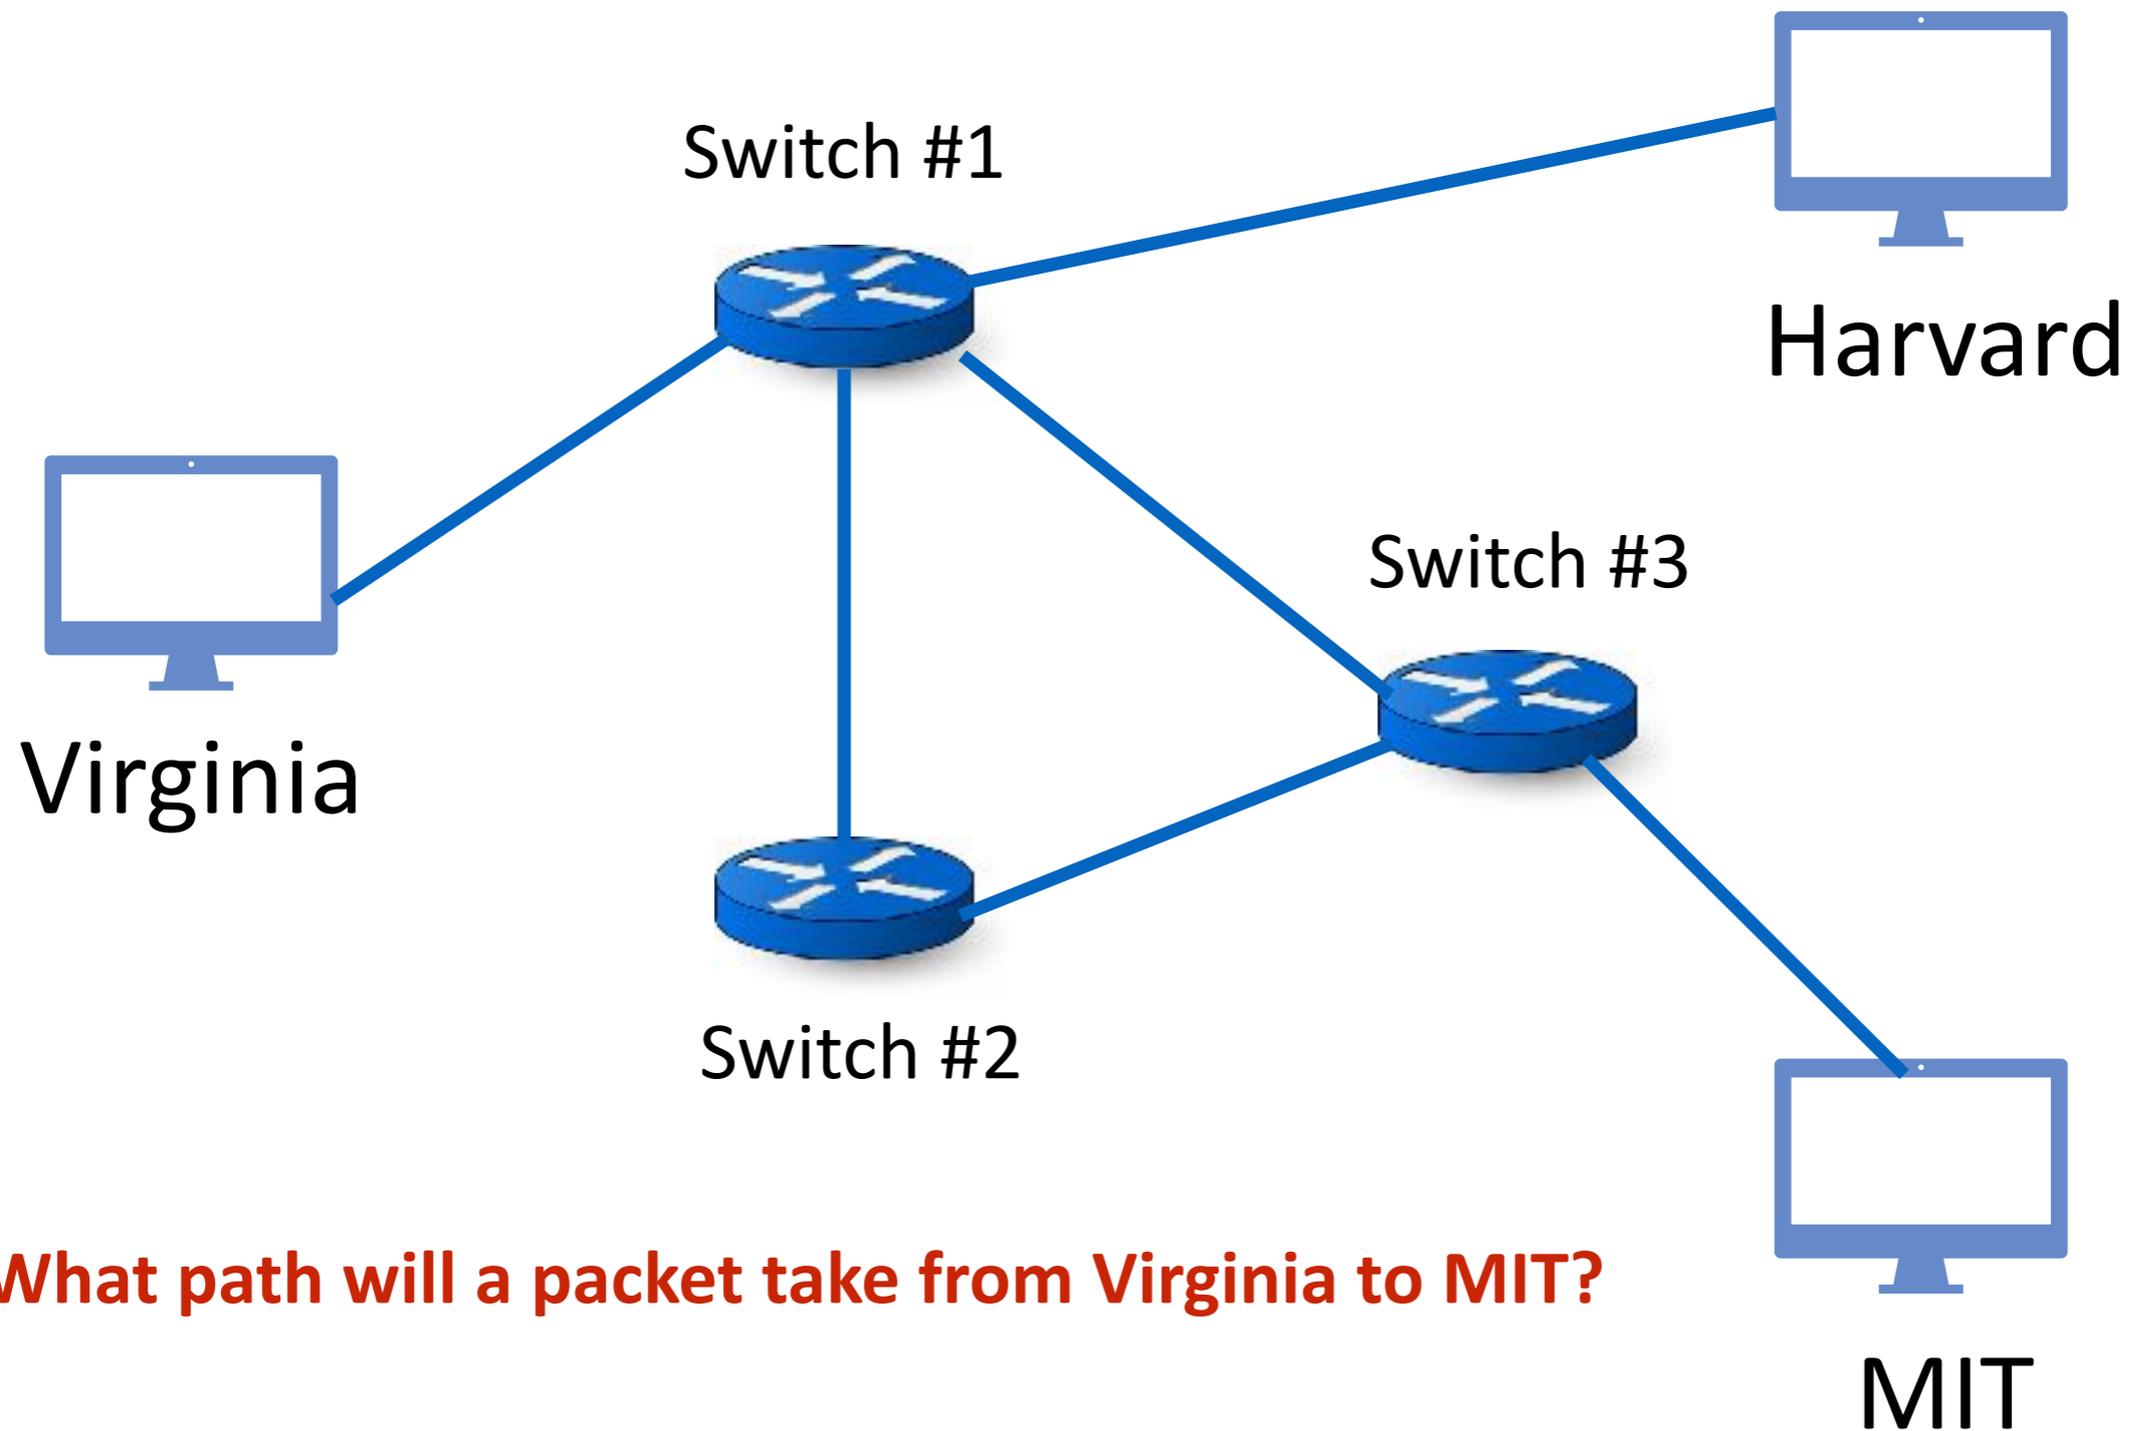

Questions?

Why do we need a network layer?

- Network layer performs “routing” of packets to alleviate these issues
- Uses routing tables
- Lets understand routing tables first

Routing Packets via Routing Tables

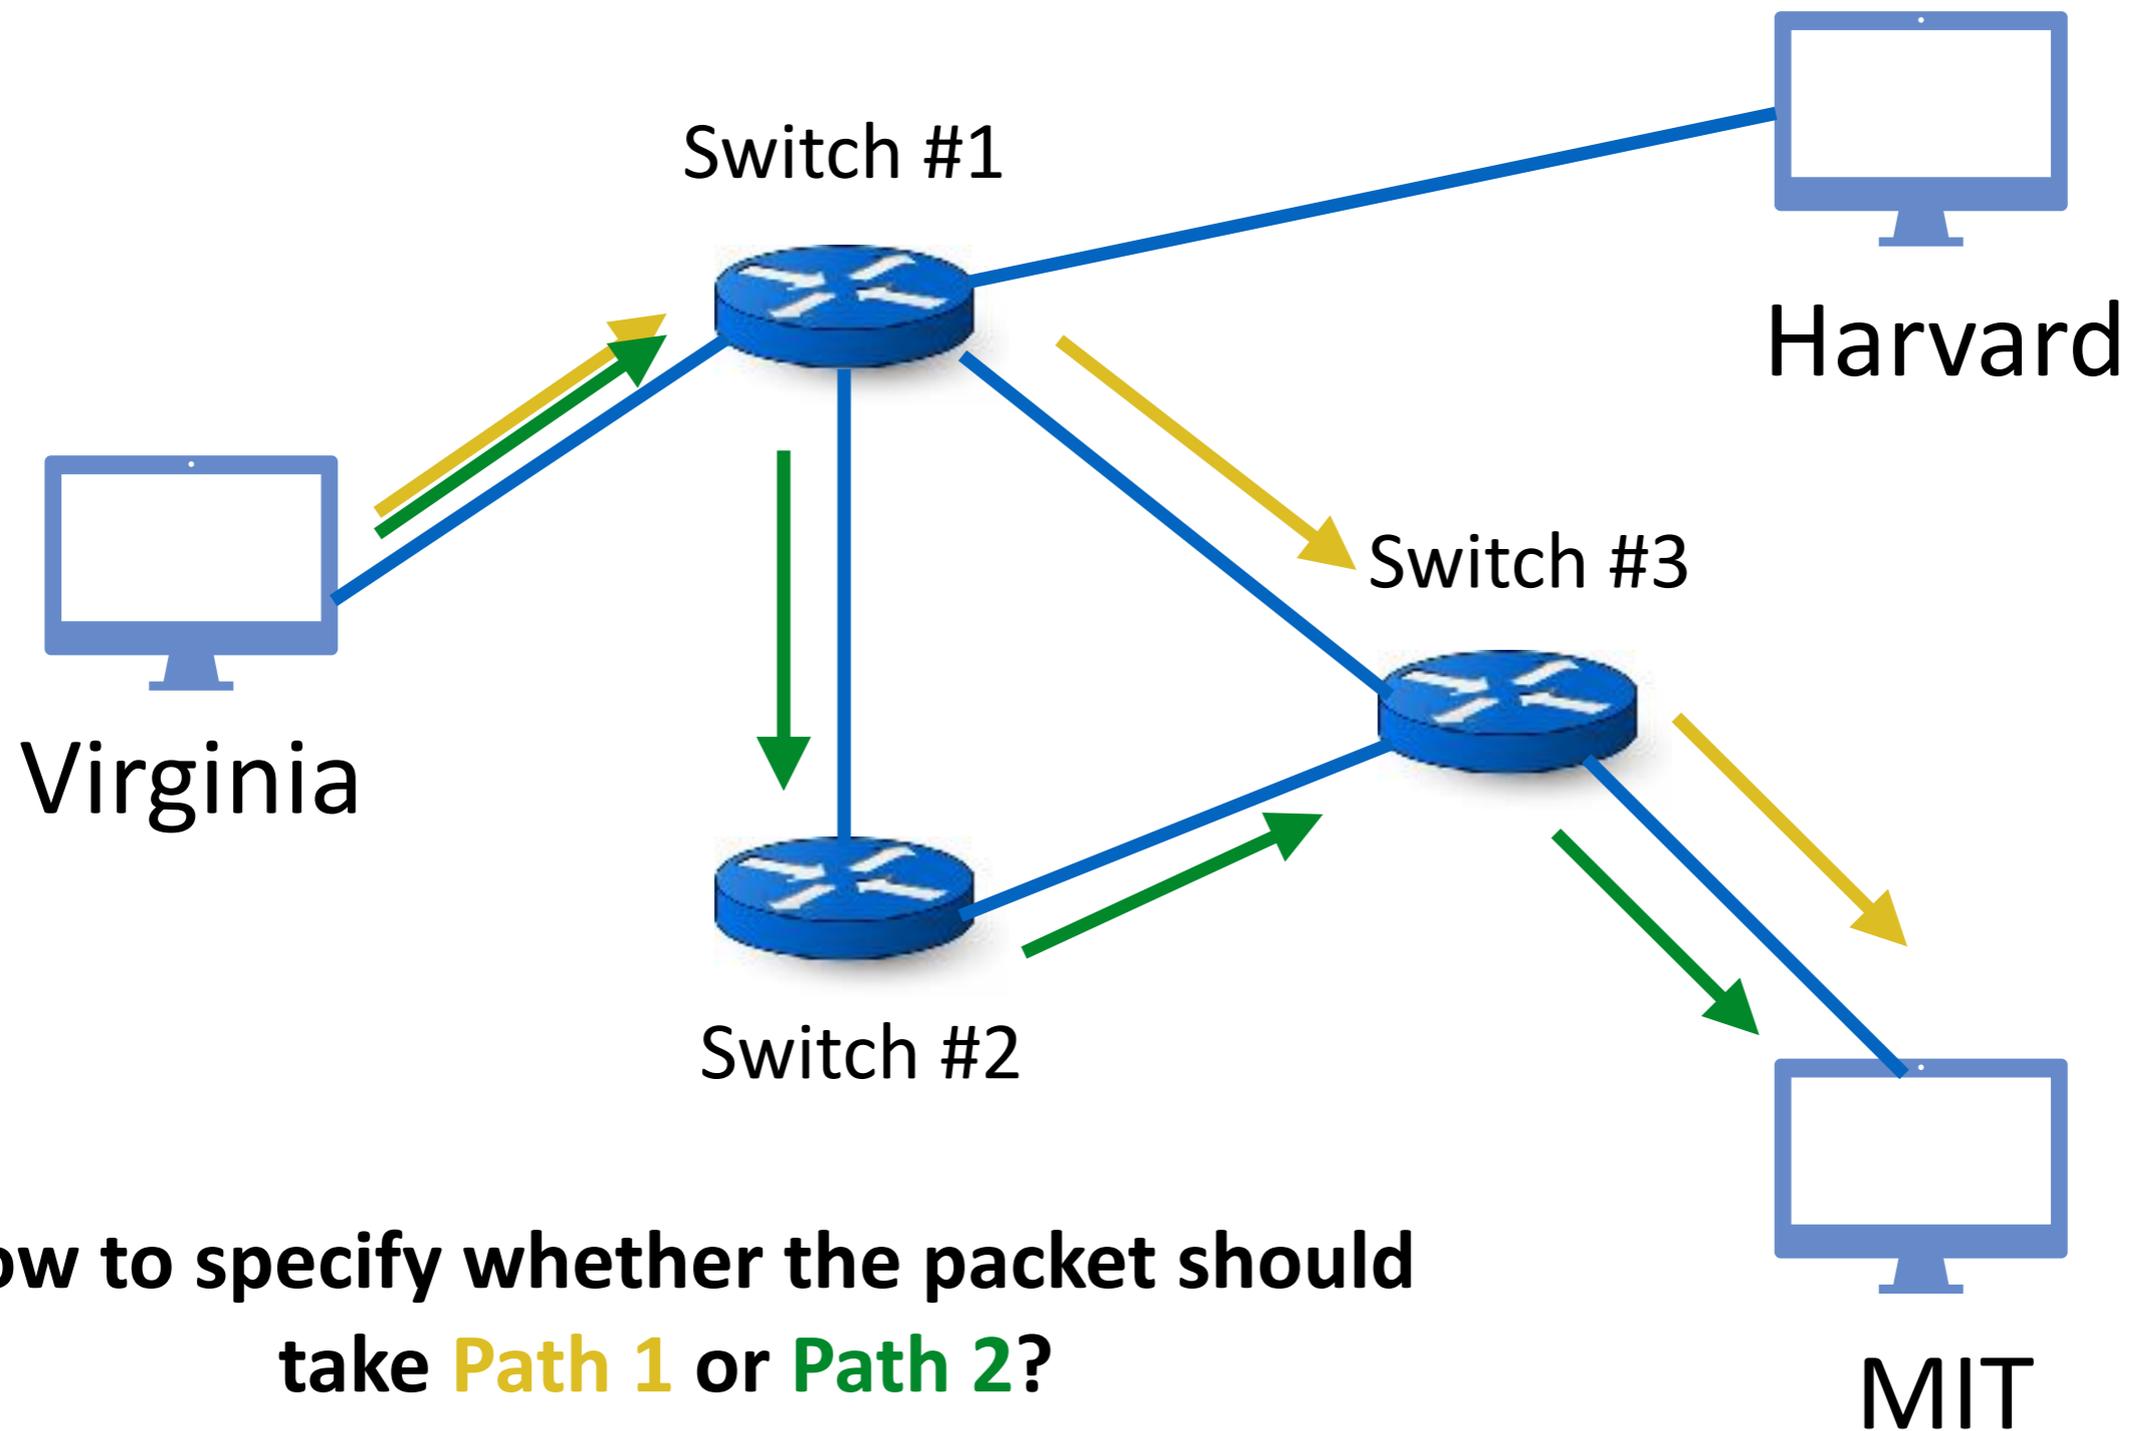

- Routing tables allow finding path from source to destination

What path will a packet take from Virginia to MIT?

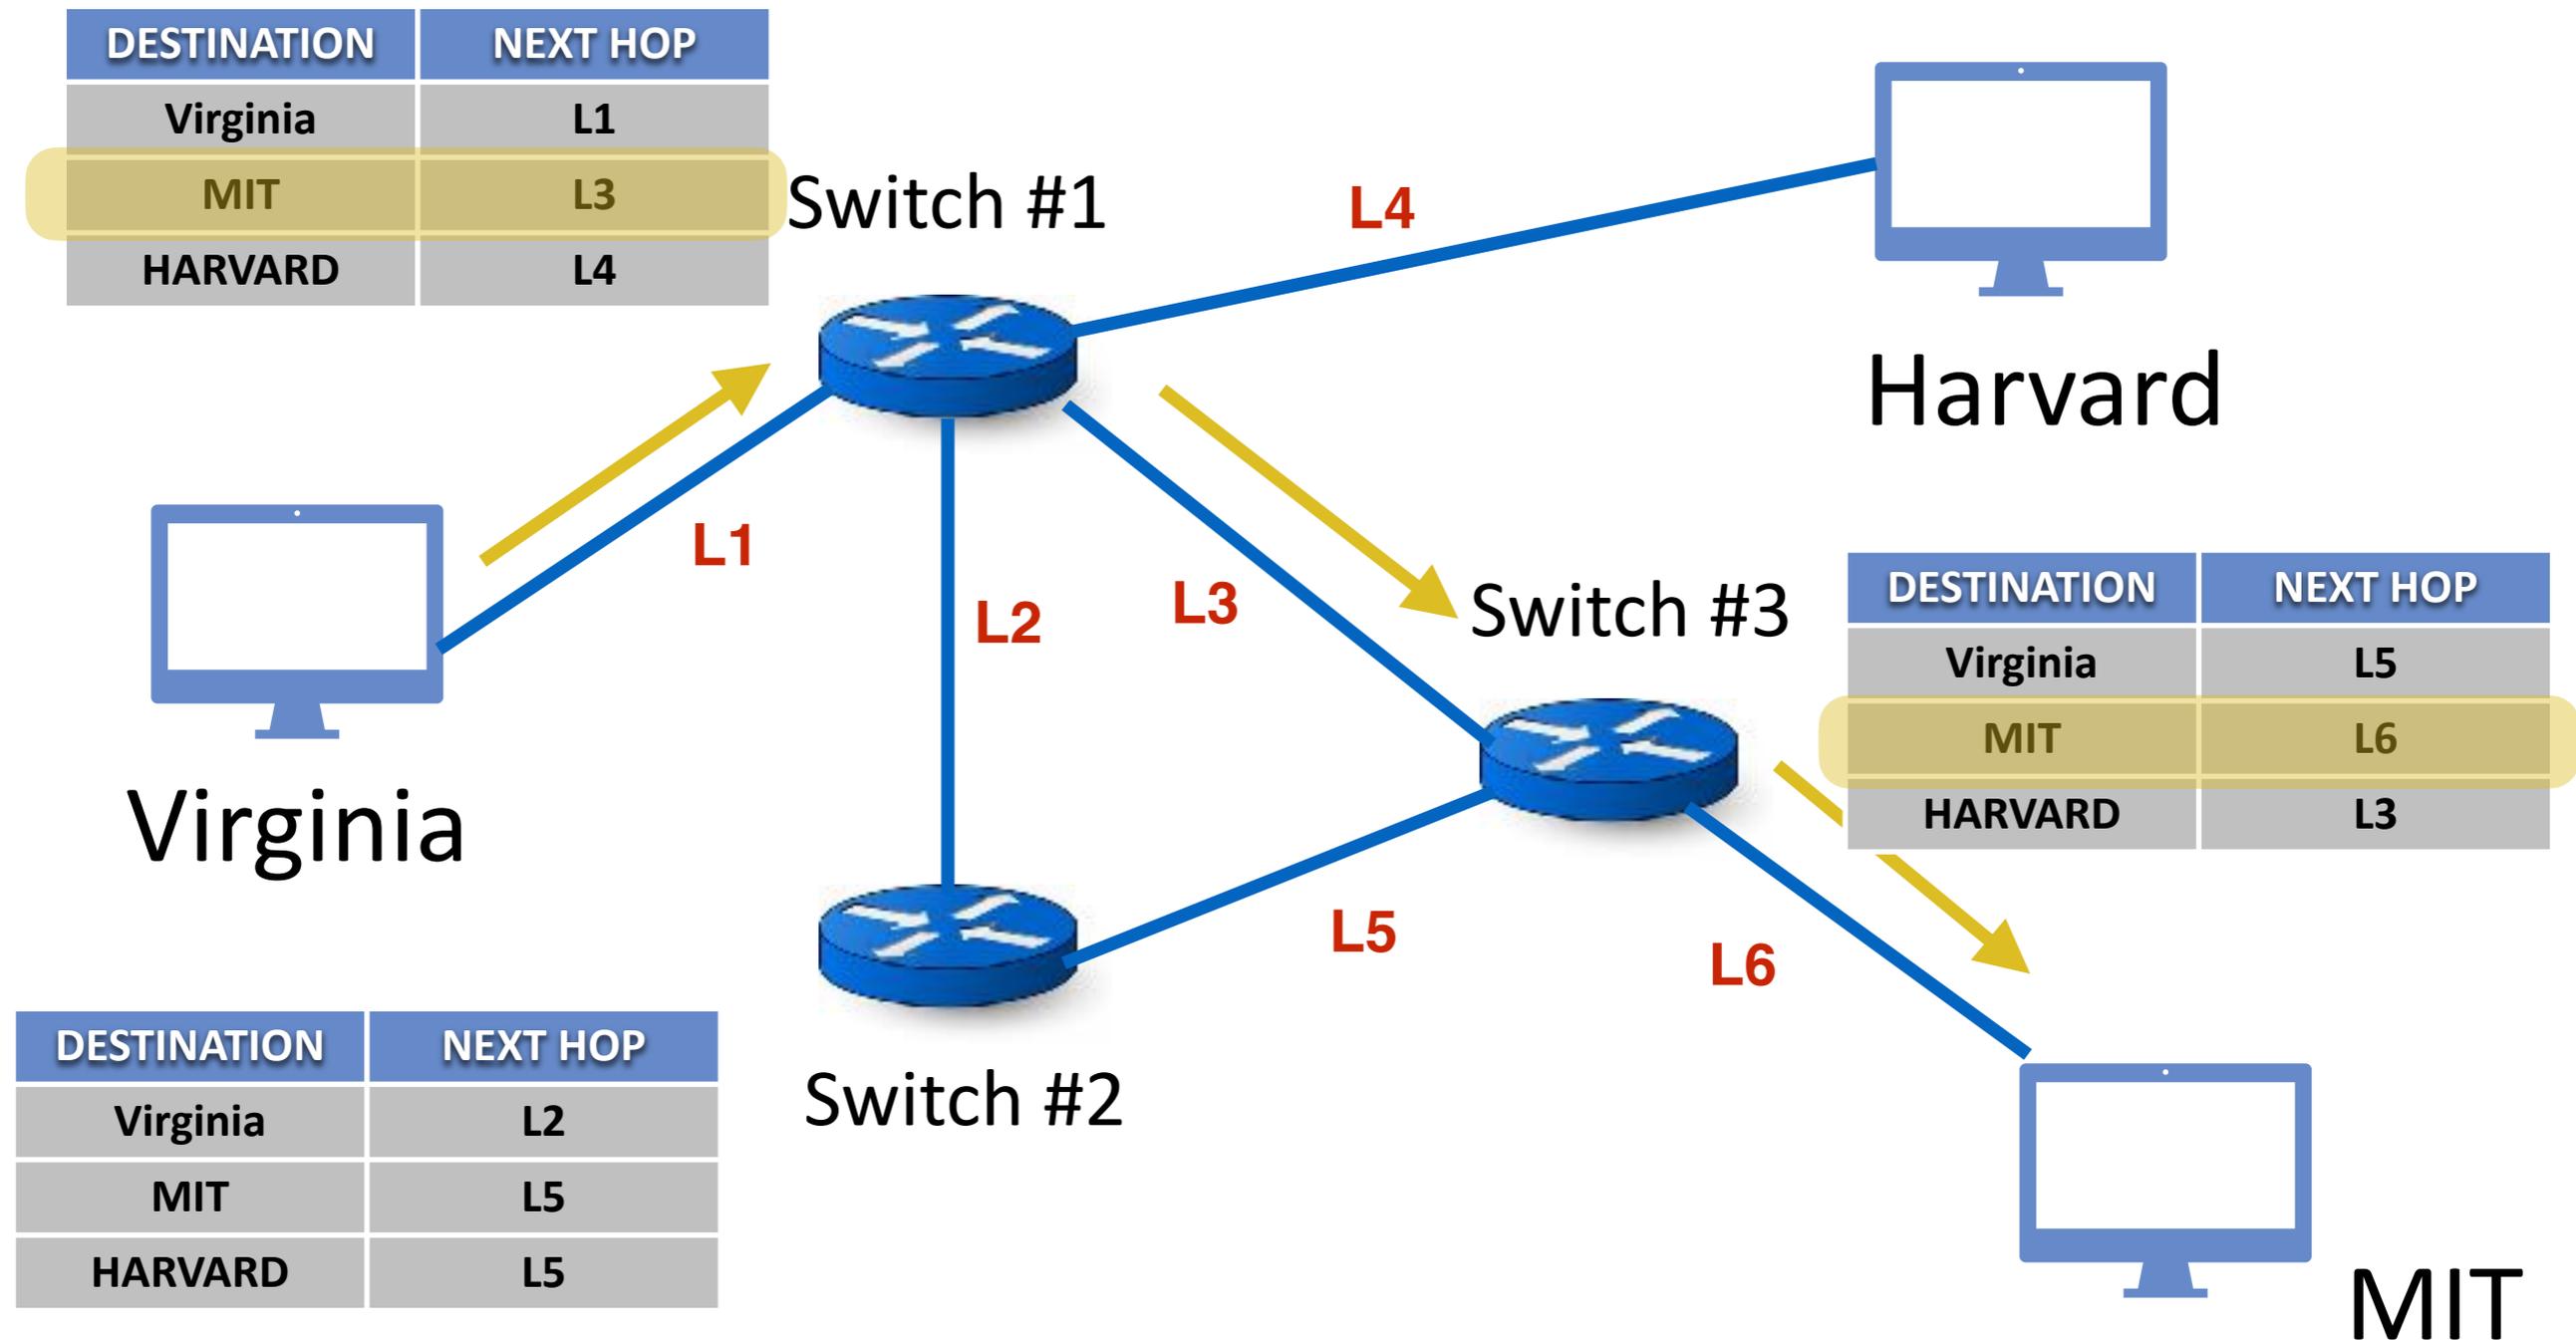

Routing Packets via Routing Tables

- Finding path for a packet from source to destination

Routing Table

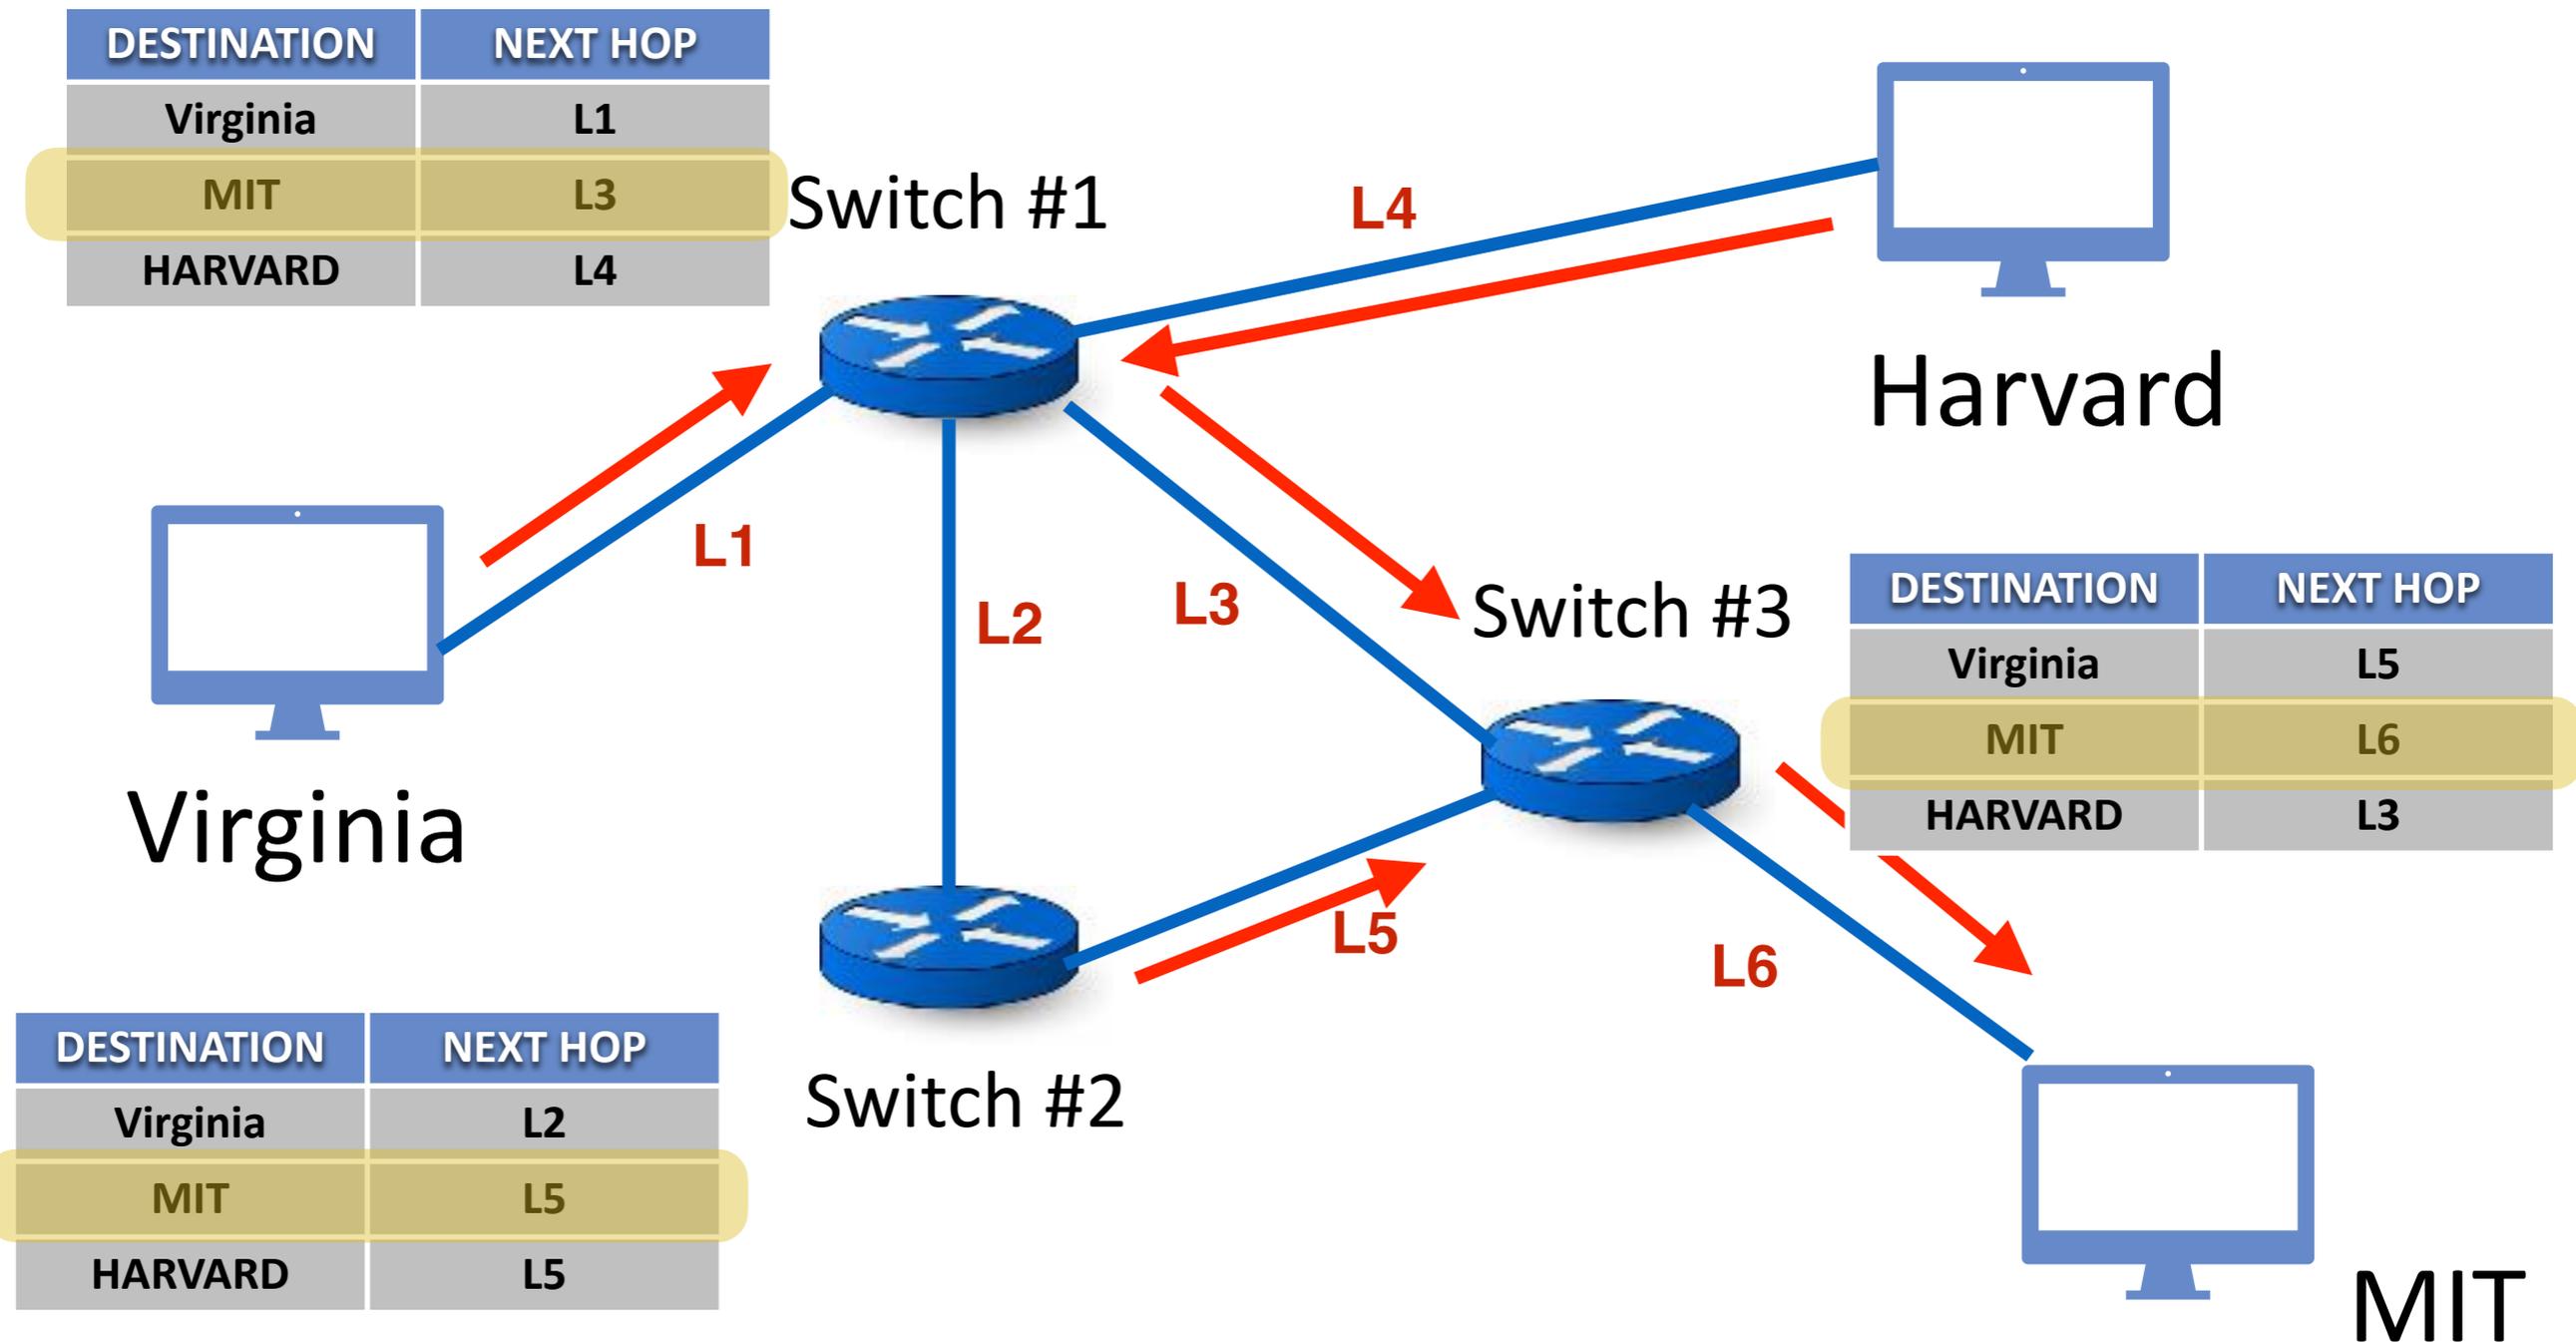

- Suppose packet follows **Path 1: Virginia - S#1 - S#3 - MIT**

Each Switch stores a table indicating the next hop for corresponding destination of a packet (called a routing table)

Routing Table: The right way to think about them

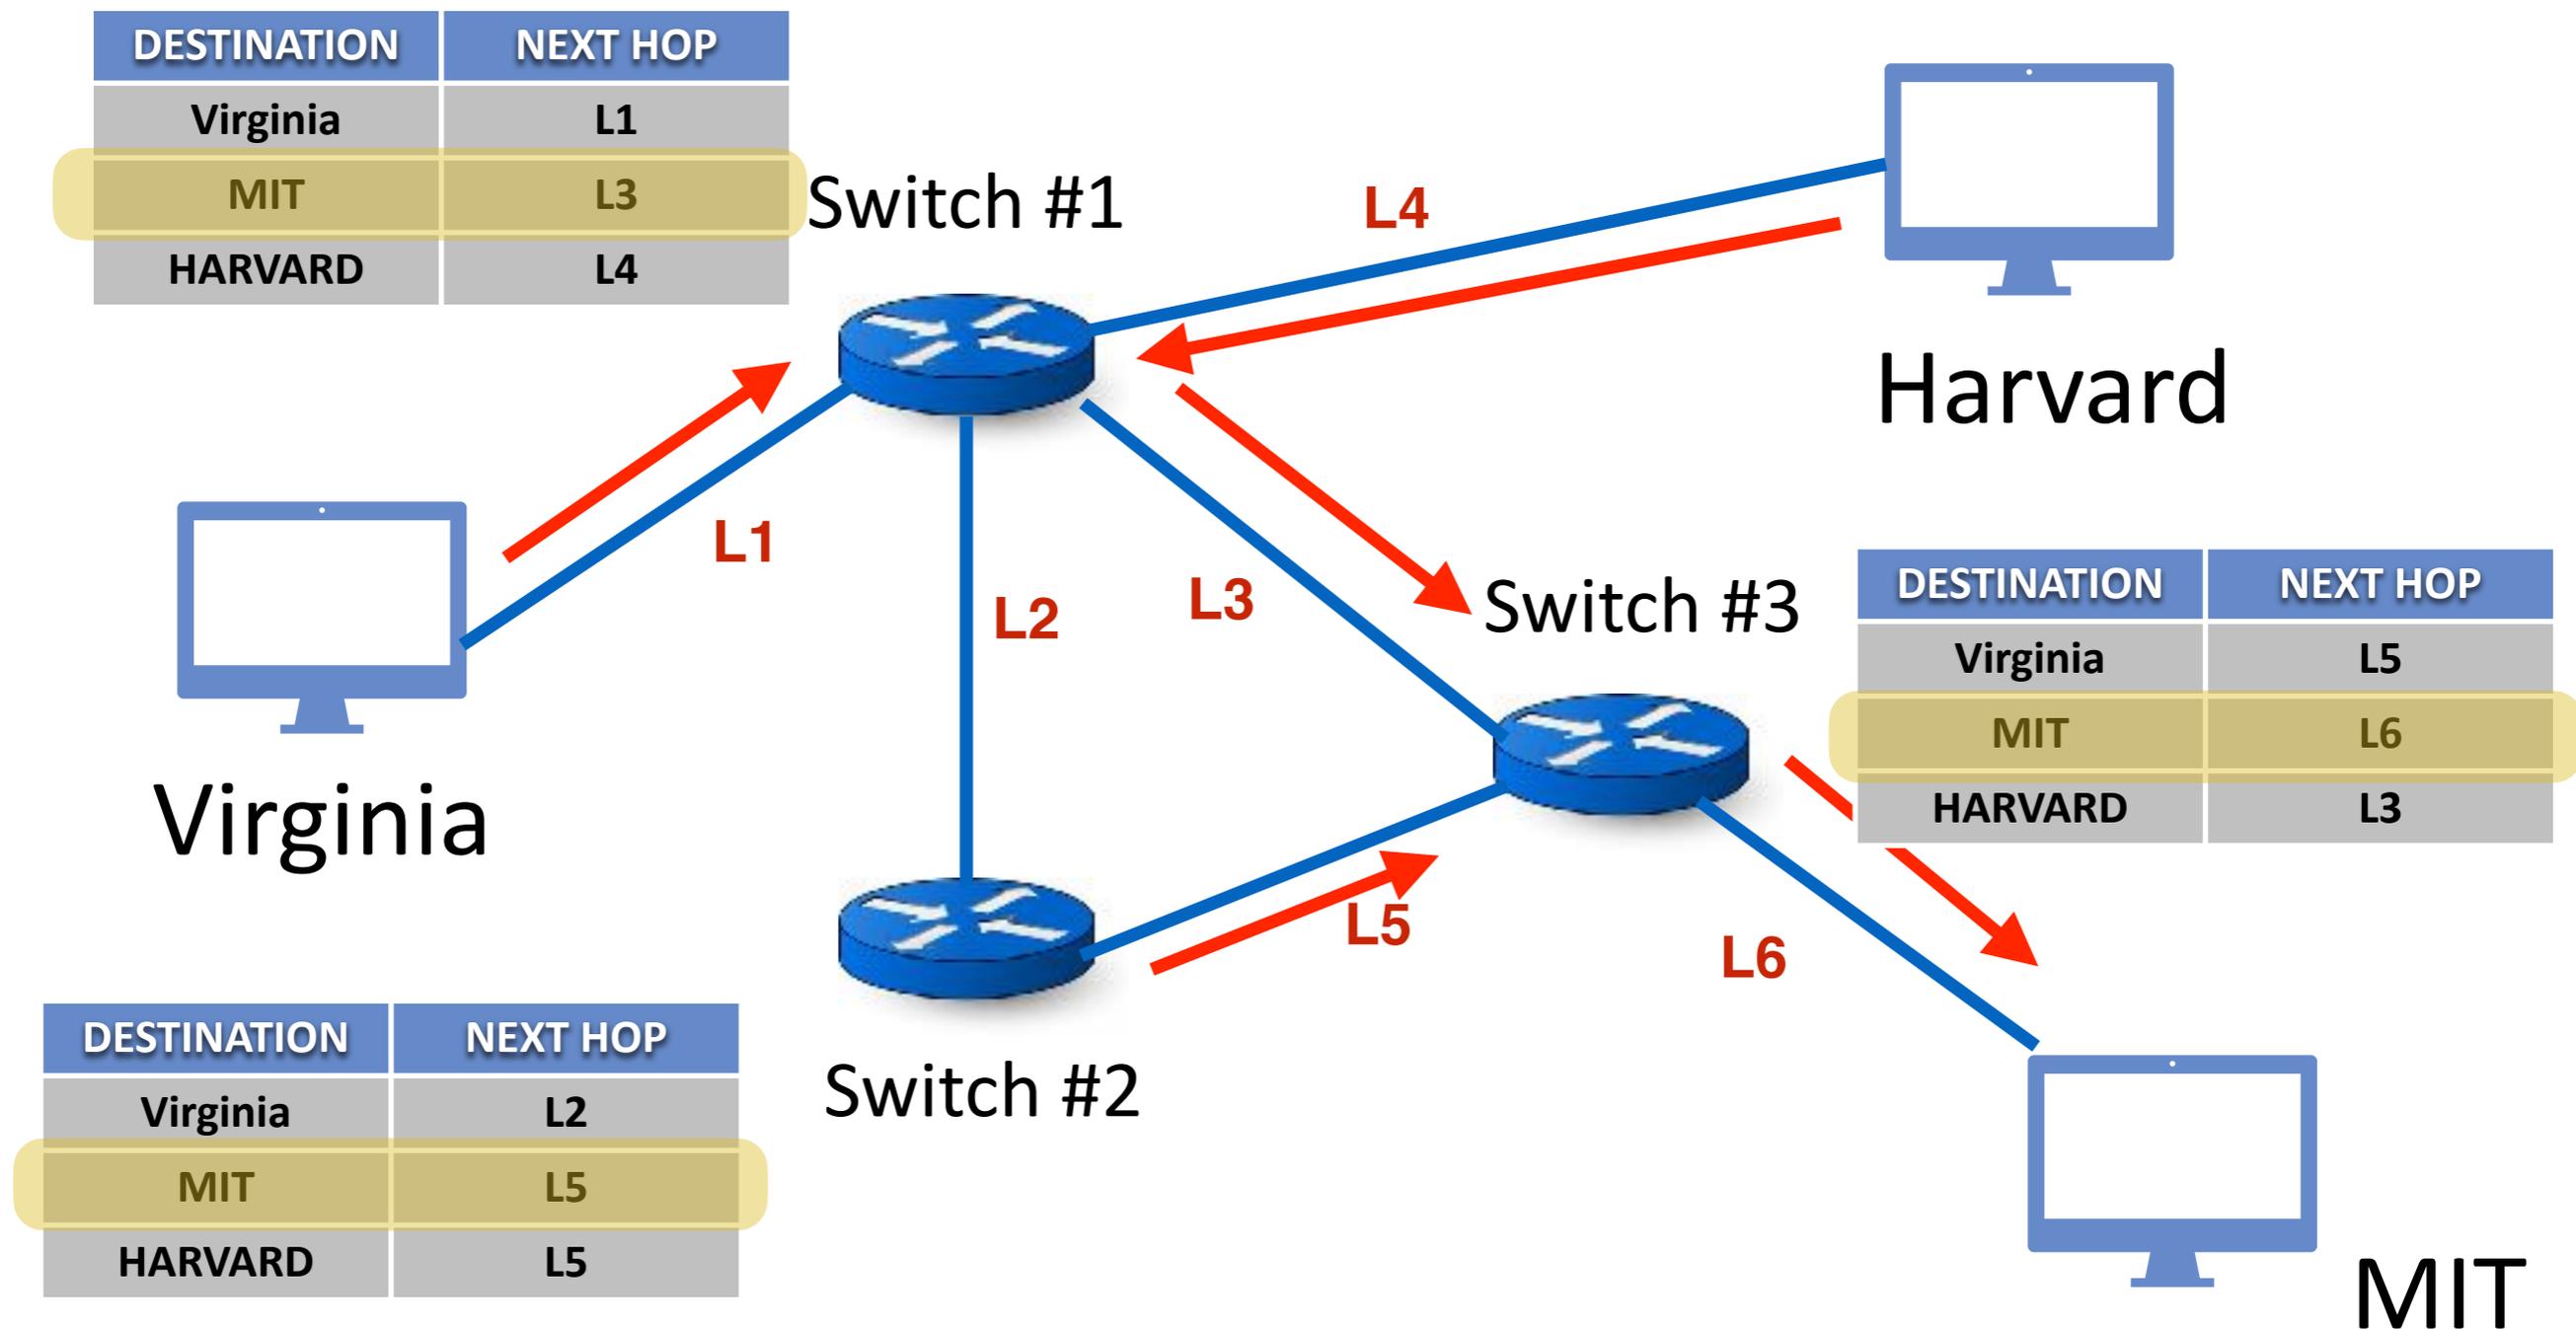

- Lets focus on one destination - MIT

See something interesting?

Routing Table: The right way to think about them

- Lets focus on one destination - MIT

Routing table entries for a particular destination form a (directed) spanning tree with that destination as the root!!!!

Routing Table: The right way to think about them

- Routing tables are nothing but
 - A collection of (directed) spanning tree
 - One for each destination
- **Routing Protocols**
 - “n” spanning tree protocols running in parallel

“Valid Routing Tables” (routing state)

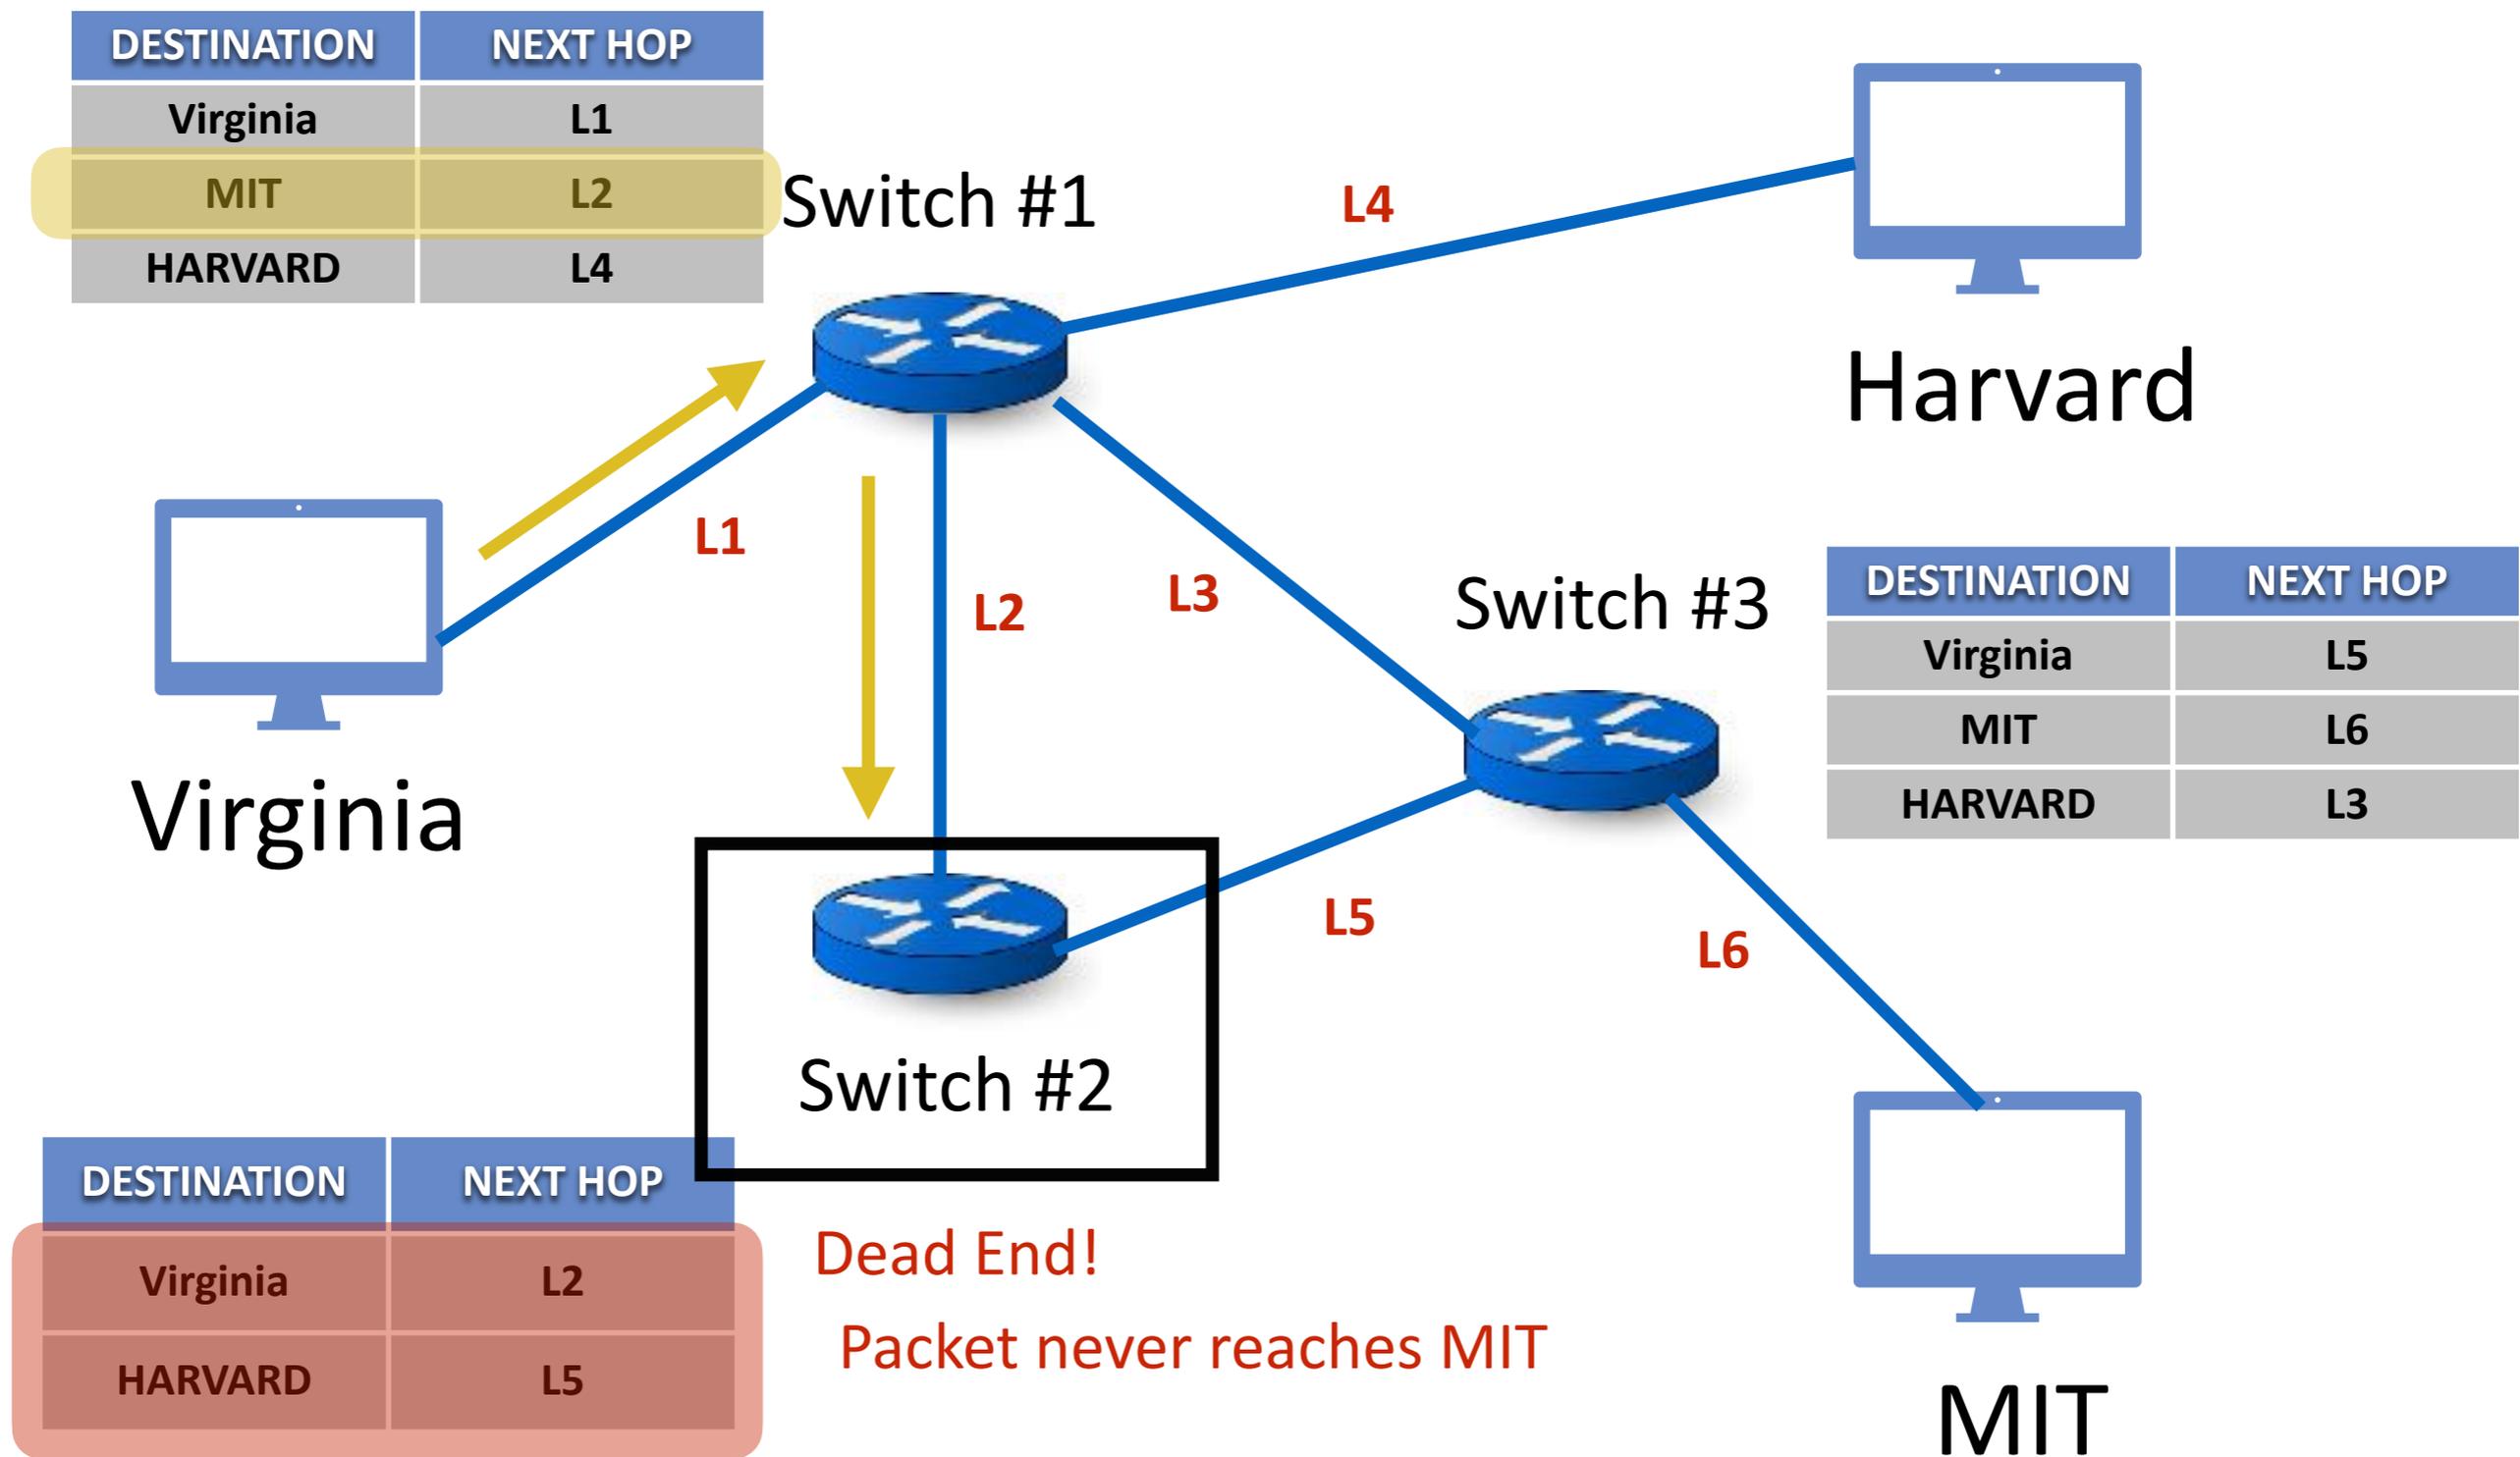

- Global routing state is valid if:
 - it **always** results in deliver packets to their destinations
- **Goal of Routing Protocols**
 - Compute a valid state
 - But how to tell if a routing state is valid?...
 - Think about it, what could make routing incorrect?

Validity of a Routing State

- Global routing state valid **if and only if**:
 - There are no **dead ends** (other than destination)
 - There are no **loops**
- A **dead end** is when there is **no outgoing link**
 - A packet arrives, but ..
 - the routing table does not have an outgoing link
 - And that node is not the destination
- A **loop** is when a **packet cycles around** the same set of nodes forever

Example: Routing with Dead Ends

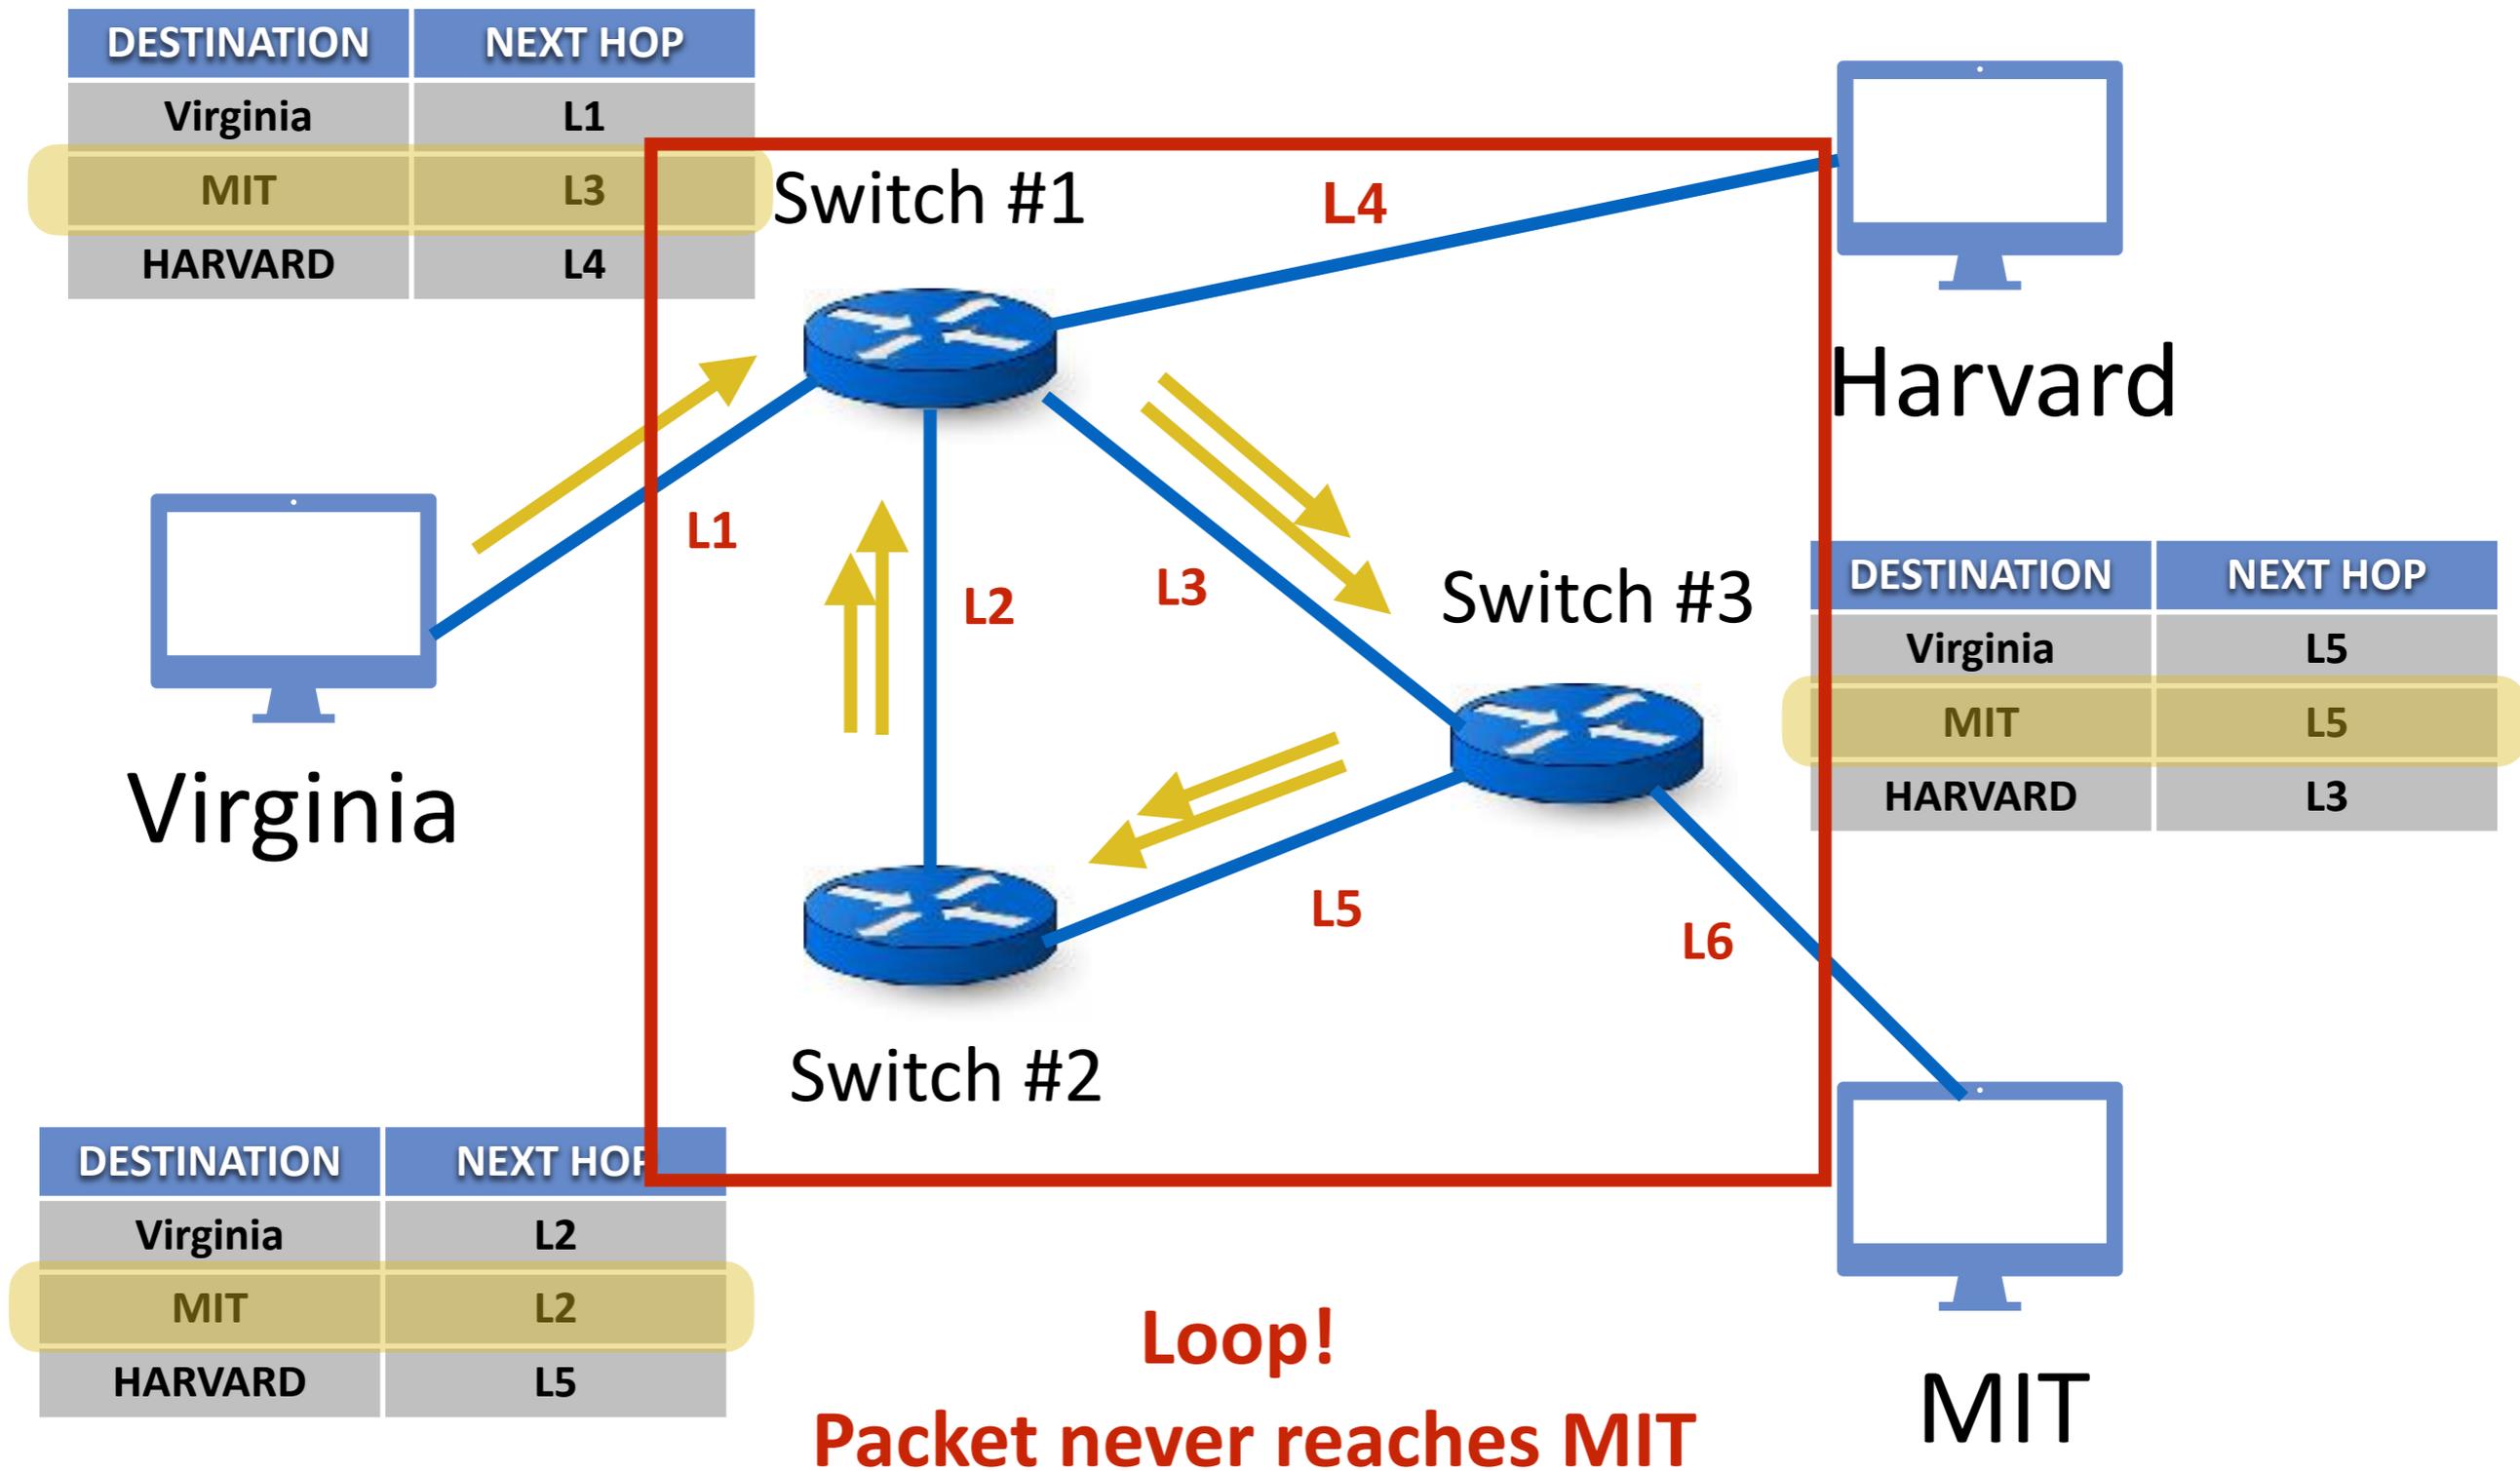

- Suppose packet wants to go from Virginia to MIT using given state:

No forwarding decision for MIT!

Example: Routing with Loops

- Suppose packet wants to go from Virginia to MIT using given state:

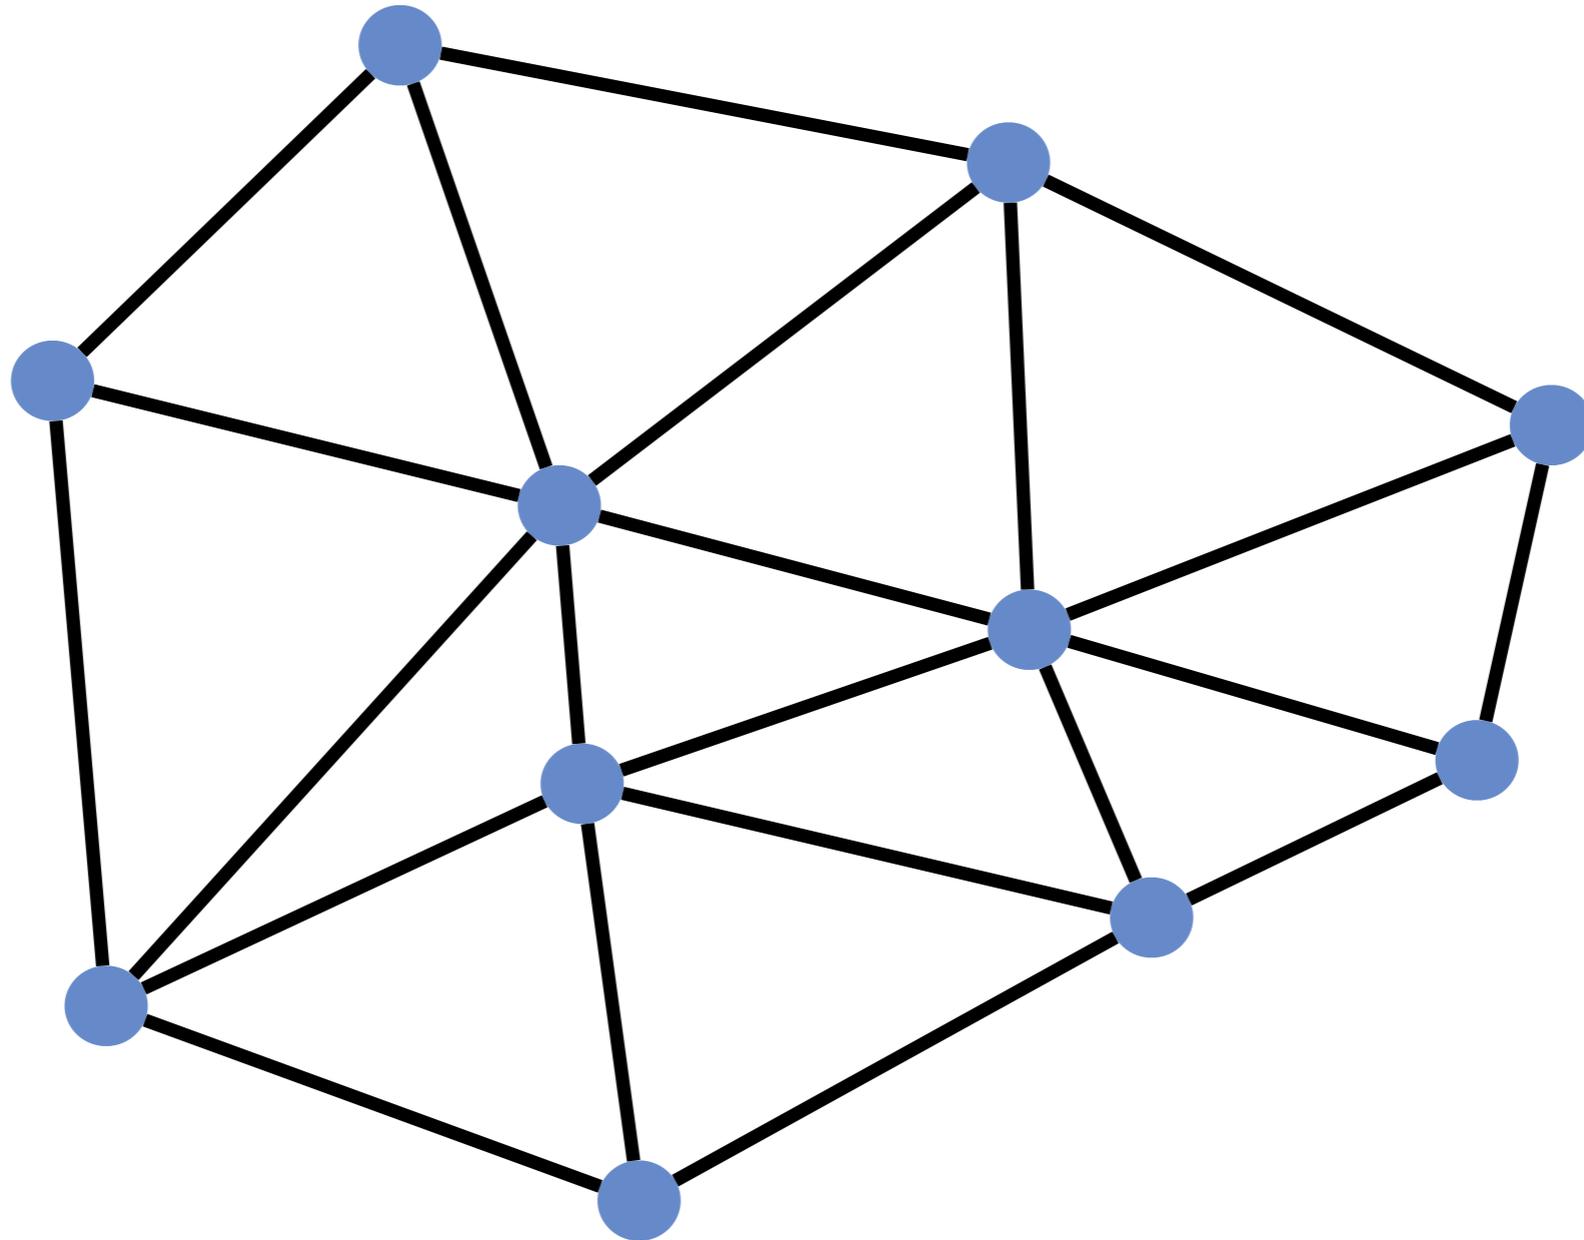

Two Questions

- How can we **verify** given routing state is valid?
- How can we **produce** valid routing state?

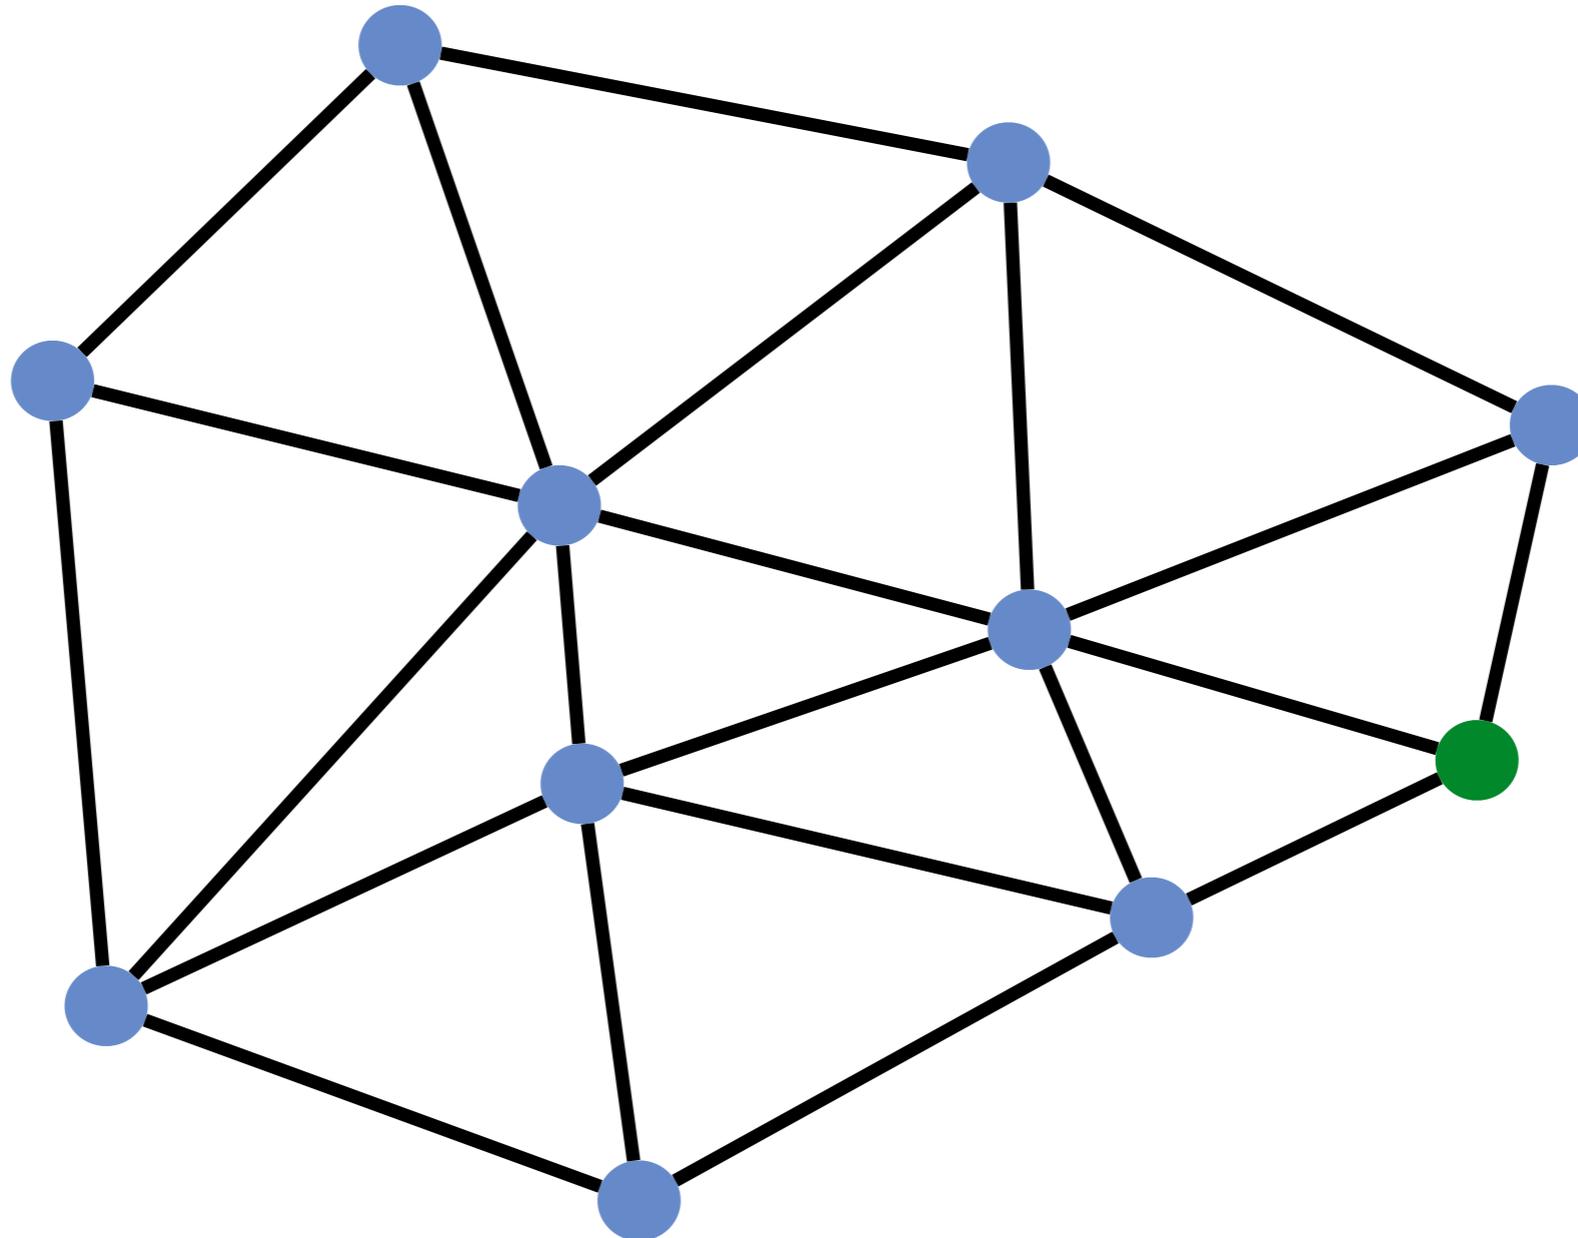

Checking Validity of a Routing State

- Check validity of routing state for one destination at a time...
- For each node:
 - Mark the outgoing link with arrow for the required destination
 - There can only be one at each node
- Eliminate all links with no arrows
- Look what's left. **State is valid if and only if**
 - Remaining graph is a spanning tree with destination as sink
 - Why is this true?
 - Tree -> No loops
 - Spanning (tree) -> No dead ends

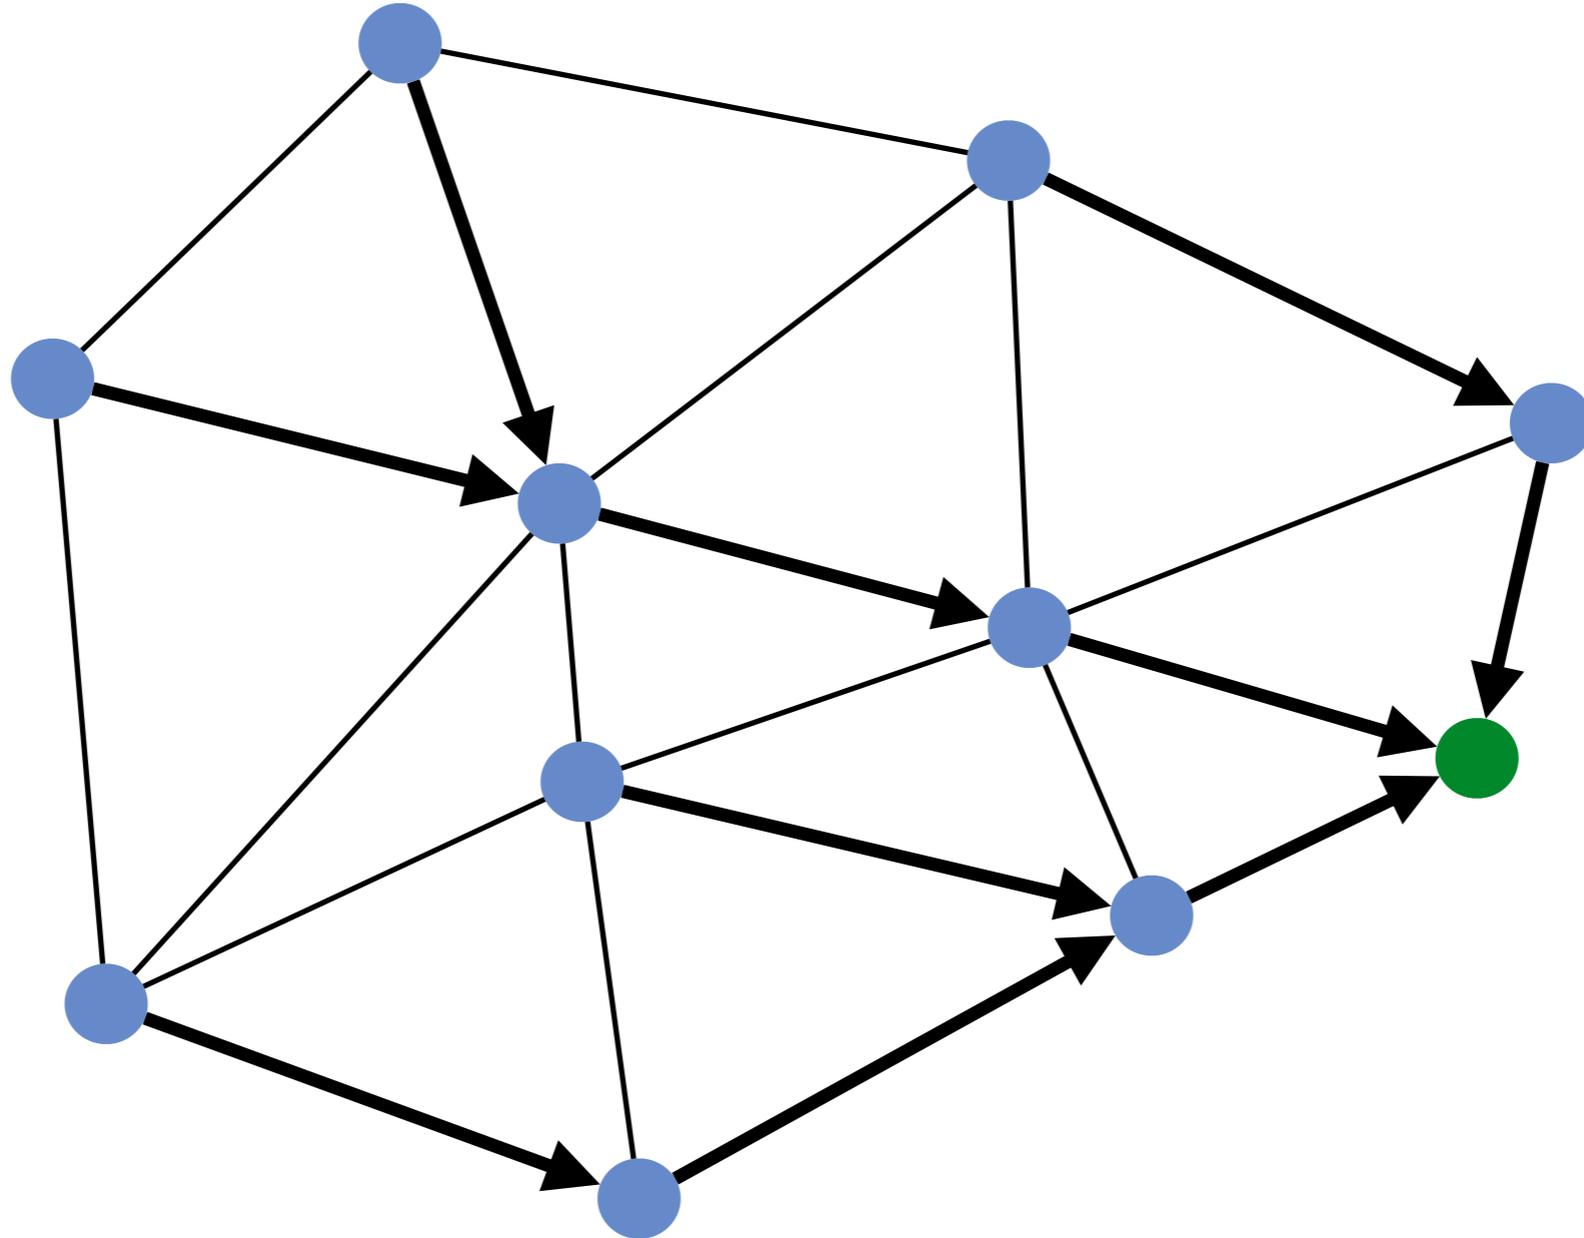

Example 1

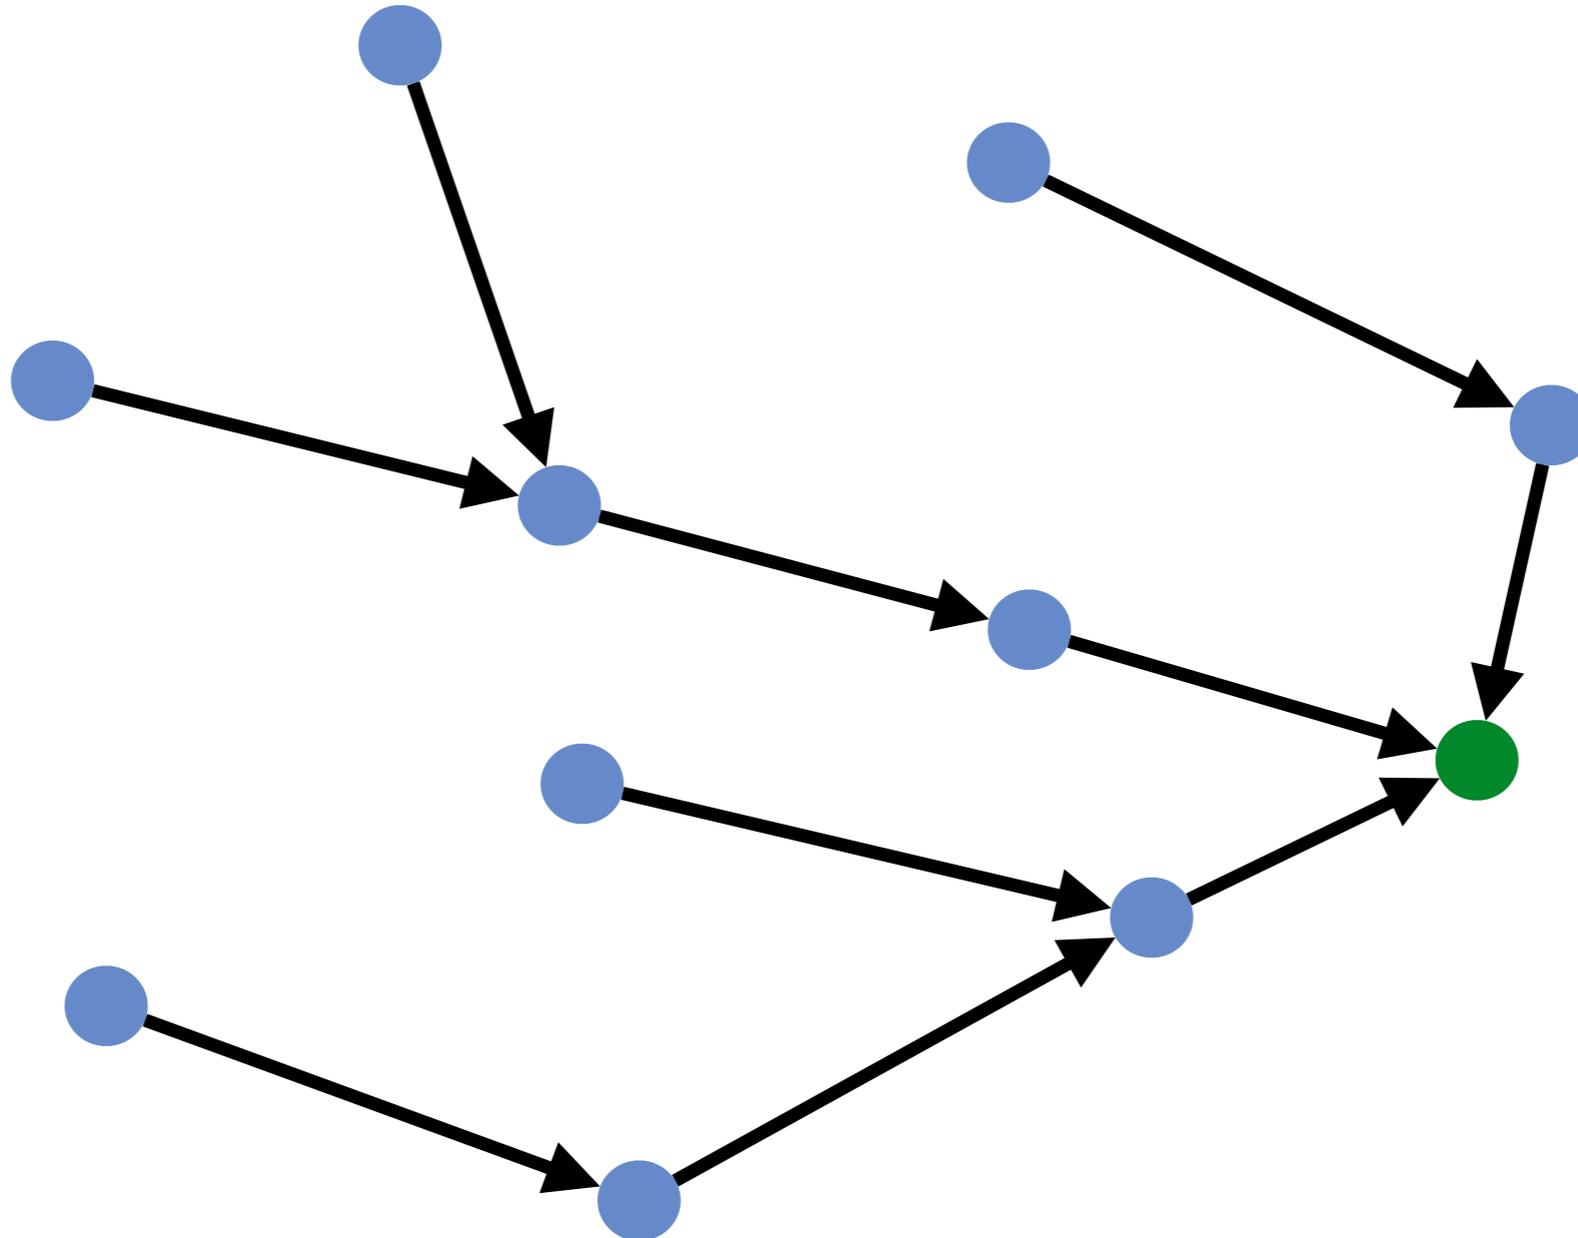

Example 1: Pick Destination

Example 1: Put Arrows on Outgoing Ports

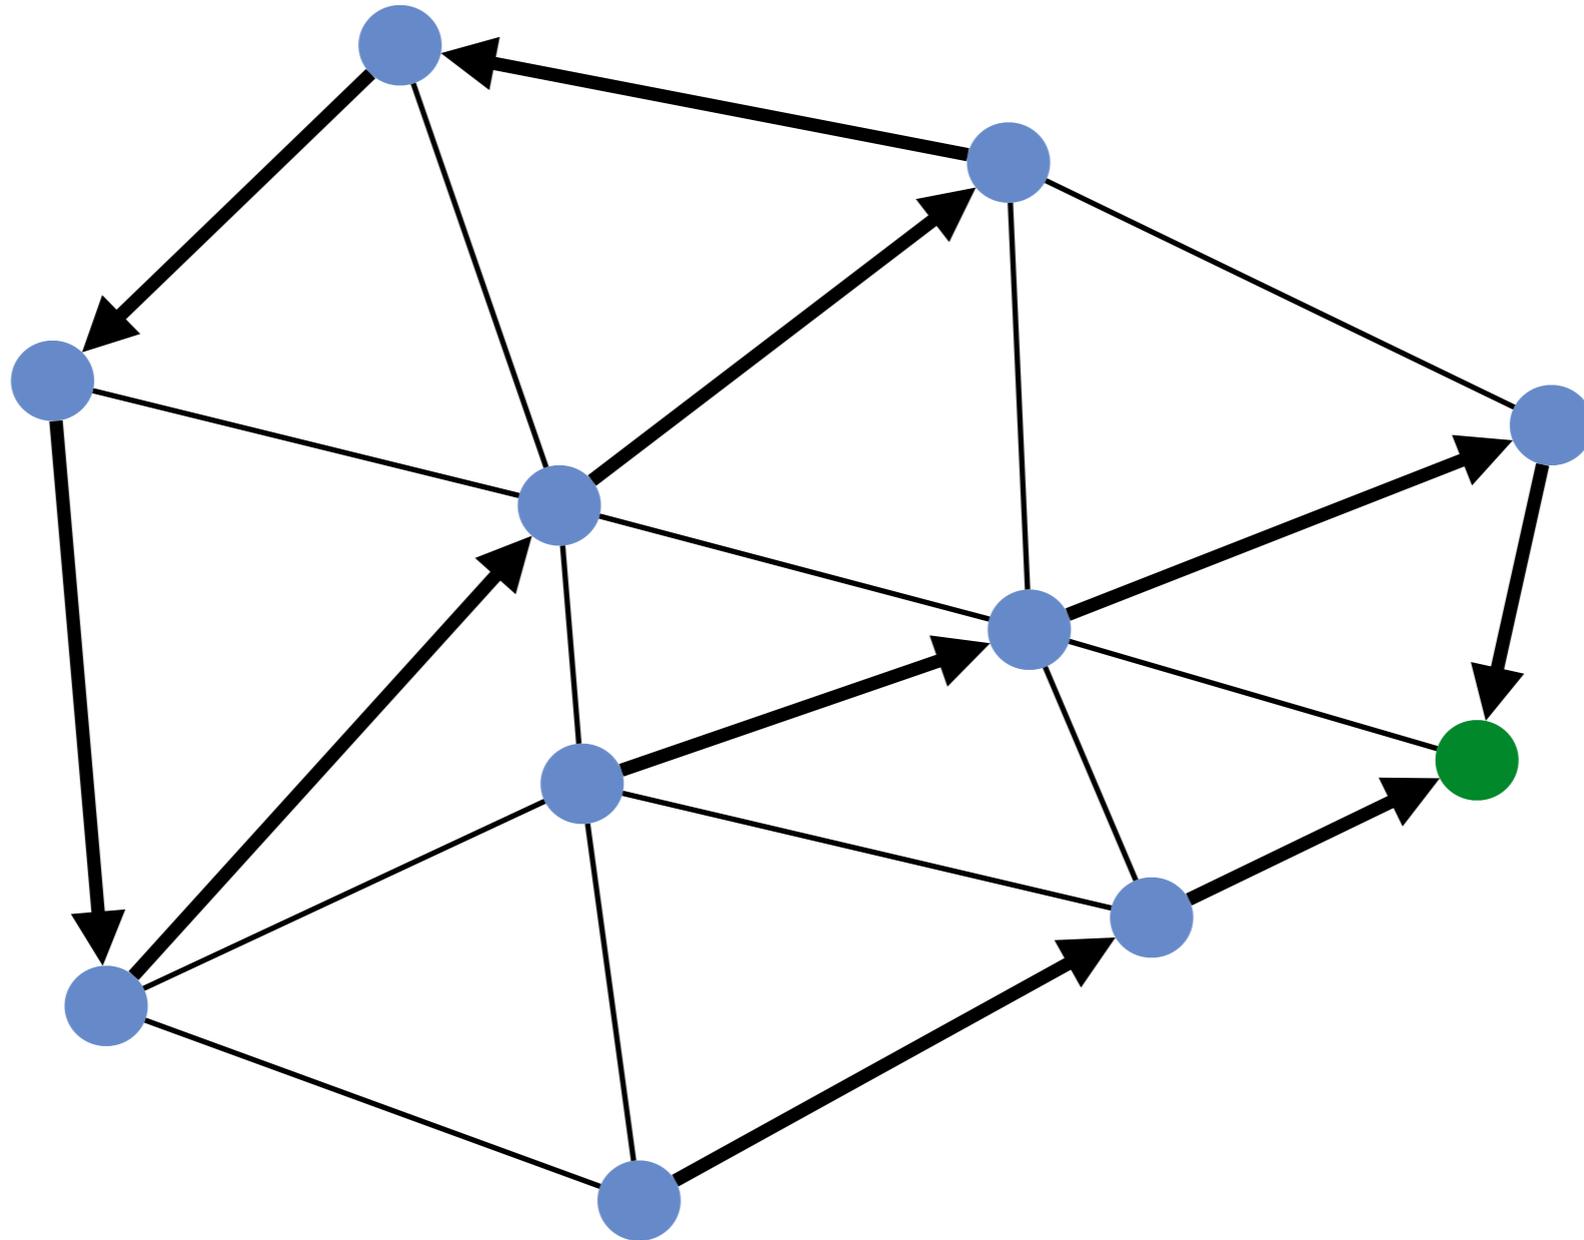

Example 1: Remove unused Links

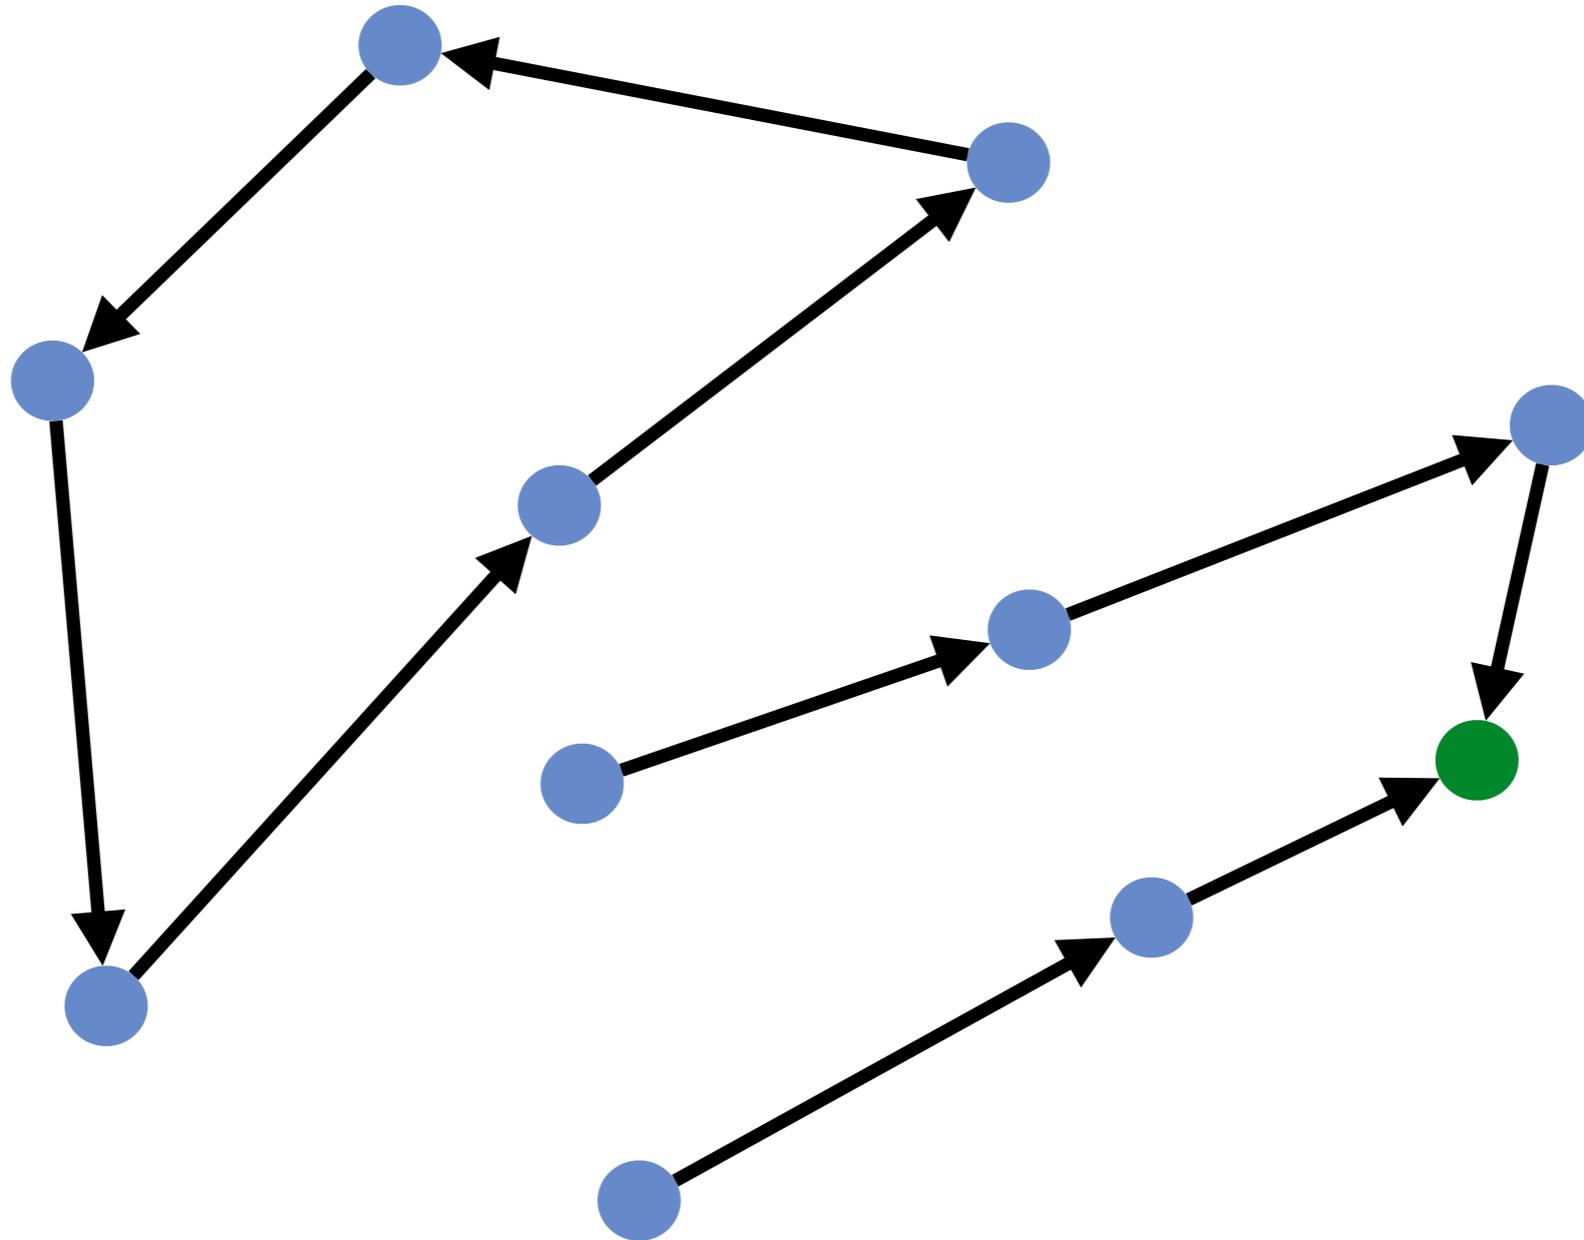

Leaves Spanning Tree: Valid

Example 2:

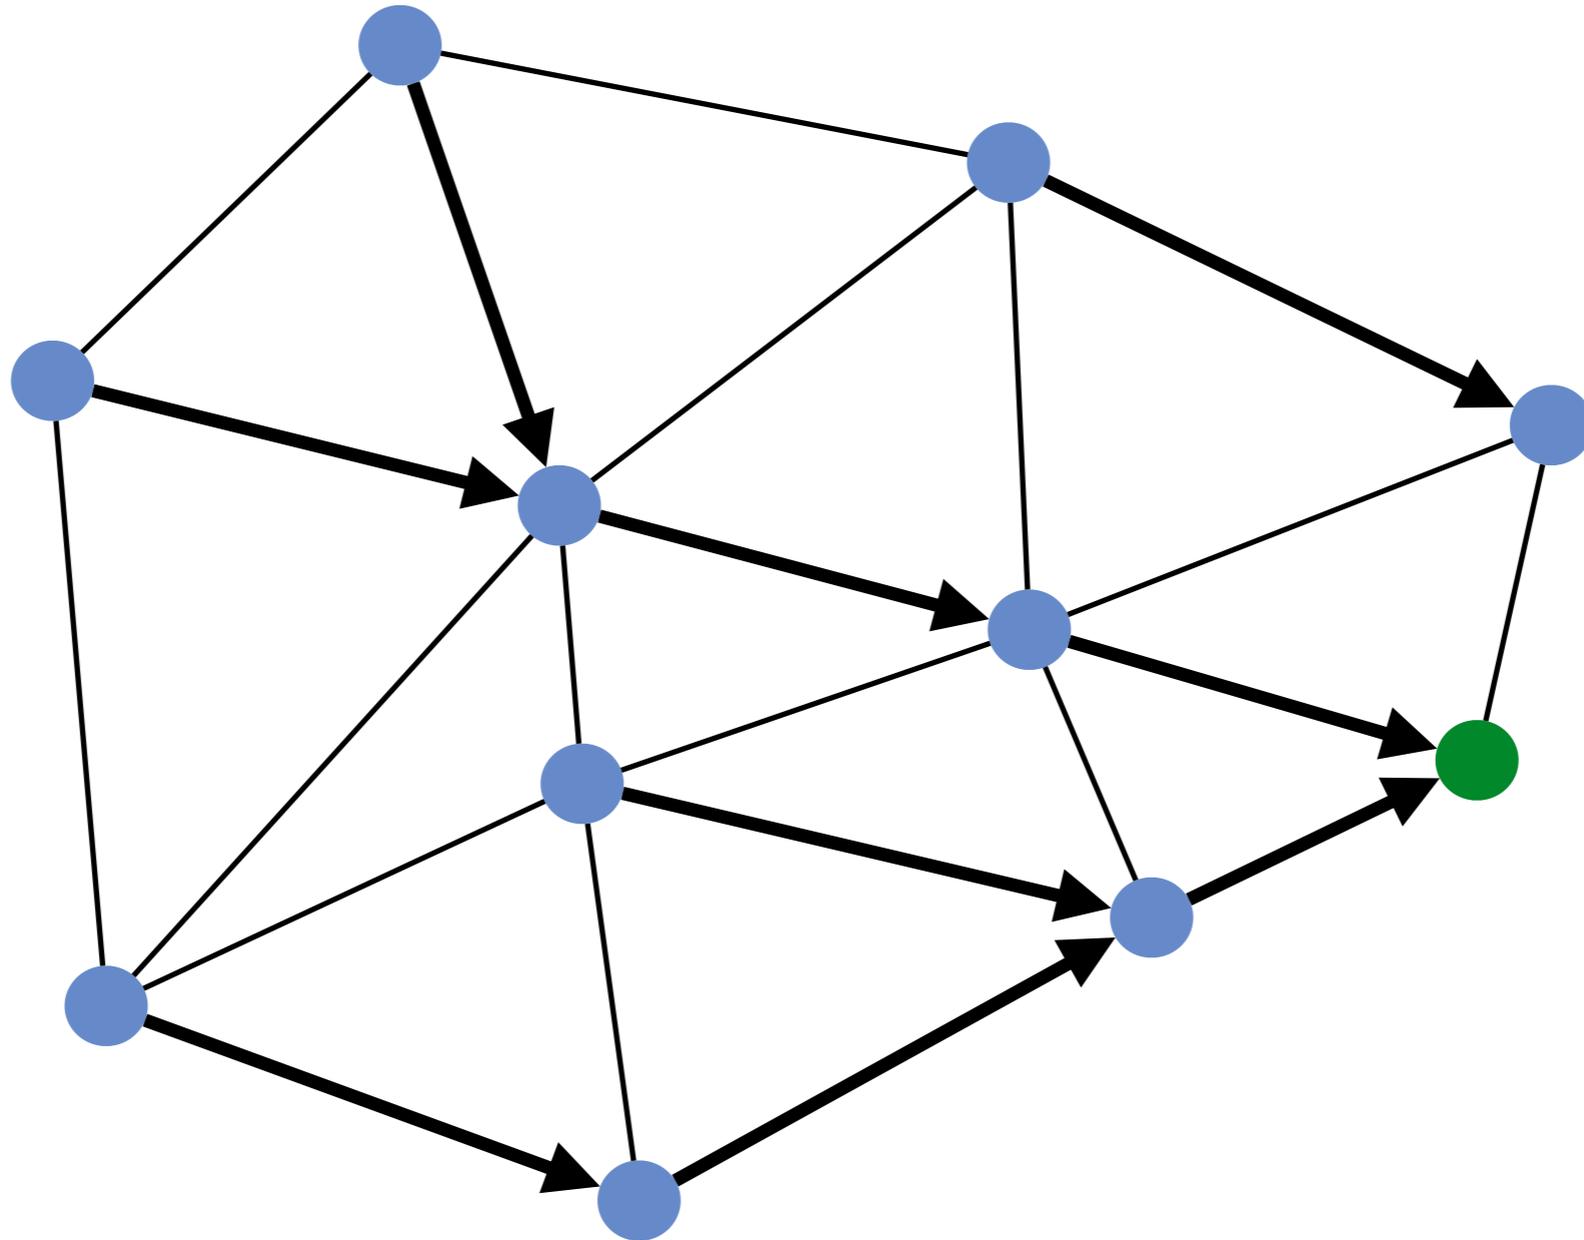

Example 2:

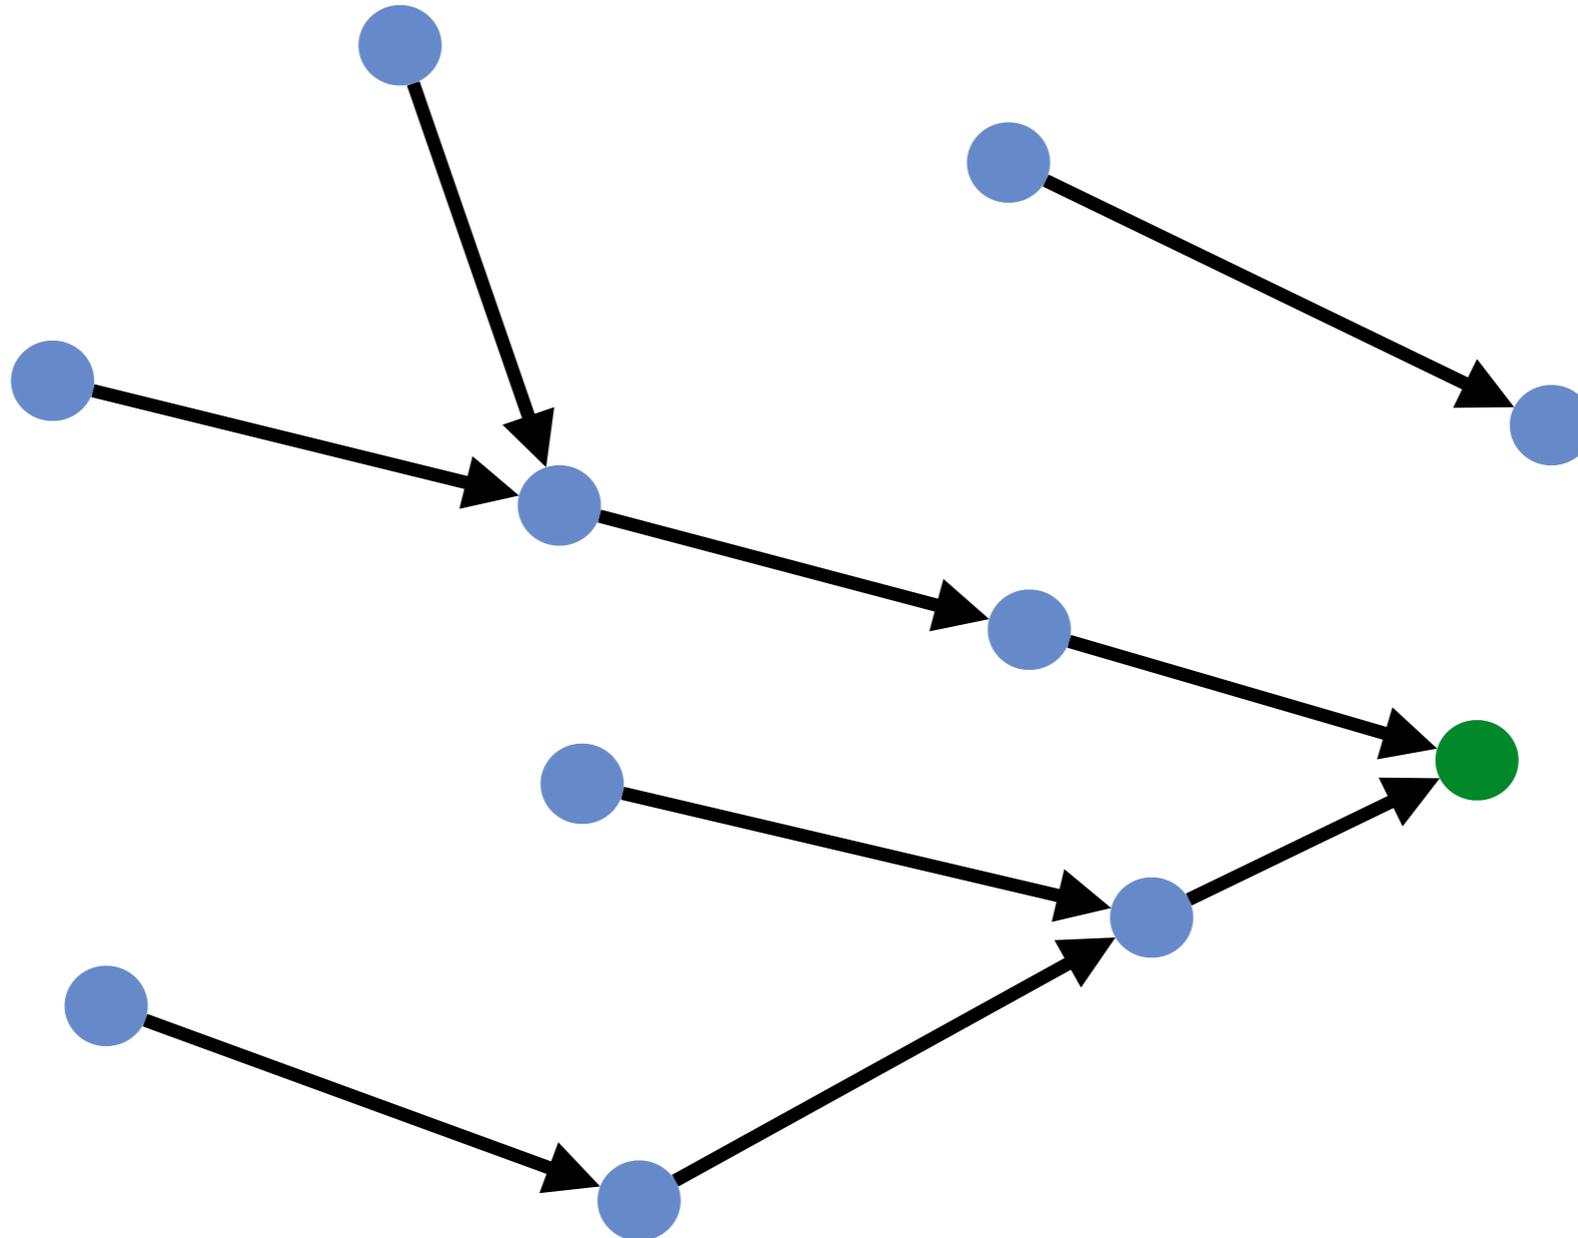

Is this valid?

Example 3:

Example 3:

Is this valid?

Checking Validity of a Routing State

- Simple to check validity of routing state for a particular destination
- Dead ends: nodes without arrows
- Loops: obvious

Two Questions

- How can we **verify** given routing state is valid?
- How can we **produce** valid routing state?

Creating Valid Routing State

- Easy to avoid dead ends
- Avoiding loops is hard
- **The key difference between routing protocols is how they avoid loops!**
- Try to think a loop avoidance design for five minutes

#1: Create Tree Out of Topology

- Remove enough links to create a tree containing all nodes
- Sounds familiar? Spanning trees!
- If the topology has no loops, then just make sure not sending packets back from where they came
 - That causes an immediate loop
- Therefore, if no loops in topology and no formation of immediate loops ensures valid routing
- However... three challenges
 - Unnecessary host resources used to process packets (assume flooding)
 - High latency
 - Low bandwidth (utilization)

#2: Obtain a Global View

- A global view of the network makes computing paths without loops easy
 - Many graph algorithms for computing loop-free paths
 - For e.g., Dijkstra's Algorithm
- Getting the global view of network is challenging!

#3: Distributed Route Computation

- Often getting a global view of the network is infeasible
 - Distributed algorithms to compute feasible route
- **Approach A:** Finding optimal route for maximizing/minimizing a metric
- **Approach B:** Finding feasible route via exchanging paths among switches

Welcome to the Network Layer!

- THE functionality: **delivering the data**
- **THE protocol: Internet Protocol (IP)**
 - To achieve its functionality (delivering the data), IP protocol has **three** responsibilities
- **Addressing (next lecture)**
- **Encapsulating data into packets (next lecture)**
- **Routing (using a variety of protocols; several lectures)**

Next lecture!
